¹AAJ15BI reports $m_{J/\psi} - m_{\eta_c(1S)} = 114.7 \pm 1.5 \pm 0.1$ MeV from a sample of $\eta_c(1S)$ and J/ψ produced in b -hadron decays. We have used current value of $m_{J/\psi} = 3096.900 \pm 0.006$ MeV to arrive at the quoted $m_{\eta_c(1S)}$ result.

²Taking into account an asymmetric photon lineshape.

³With floating width.

⁴ Ignoring possible interference with the non-resonant 0^- amplitude.

⁵ Using both, $\eta \rightarrow \gamma\gamma$ and $\eta \rightarrow \pi^+ \pi^- \pi^0$ decays.

⁶From a simultaneous fit to six decay modes of the η_C .

⁷Accounts for interference with non-resonant continuum.

⁸ Taking into account interference with the

⁹From a fit of the J/ψ recoil mass spectrum. Supersedes ABE,k

¹⁰ Using mass of $\psi(2S) = 3686.00$ MeV.
¹¹ Not independent from the measurements reported by LEES ¹⁰.
¹² Not independent from the measurements reported by LEES ¹⁰.

¹² MITCHELL 09 observes a significant asymmetry in the lineshapes of $\psi(2S) \rightarrow \psi(1S)\gamma$ and $\psi(3S) \rightarrow \psi(1S)\gamma$ transitions. If indeed, this asymmetry could lead to signif-

and $J/\psi \rightarrow \gamma\eta_C$ transitions. If ignored, this asymmetry could lead to significant errors in the mass and width measurements whenever the mass and width are measured in $\psi(2S)$ or J/ψ radiative decays.

¹³From the fit of the kaon momentum spectrum. Systematic errors not evaluated.

14 Superseded by LEFS 1.0

¹⁵From a simultaneous fit of five decay modes of the η_c .

¹⁶ Superseded by VINOKUROVA 11.

¹⁷Weighted average of the $\psi(2S)$ and $J/\psi(1S)$ samples. Using an η_c width of 13.2 MeV.

¹⁸ Average of several decay modes. Using an η_c width of 13.2 MeV.

¹⁹ Superseded by ASNER 04.

²⁰ Average of several decay modes.

$$^{21}\eta_c \rightarrow \phi\phi.$$

²² Mass adjusted by us to correspond to $J/\psi(1S)$ mass = 3097 MeV.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 8 combinations of partial widths obtained from integrated cross section, and 19 branching ratios uses 85 measurements and one constraint to determine 13 parameters. The overall fit has a $\chi^2 = 118.3$ for 73 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

¹ ABLIKIM 12N reports $[\Gamma(\eta_c(1S) \rightarrow p\bar{p})/\Gamma_{\text{total}}] \times [\Gamma(h_c(1P) \rightarrow \eta_c(1S)\gamma)/\Gamma_{\text{total}} \times \Gamma(\psi(2S) \rightarrow \pi^0 h_c(1P))/\Gamma_{\text{total}}] = (0.65 \pm 0.19 \pm 0.10) \times 10^{-6}$ which we divide by our best value $\Gamma(h_c(1P) \rightarrow \eta_c(1S)\gamma)/\Gamma_{\text{total}} \times \Gamma(\psi(2S) \rightarrow \pi^0 h_c(1P))/\Gamma_{\text{total}} = (4.3 \pm 0.4) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

² The quoted branching ratios use $B(J/\psi(1S) \rightarrow \gamma \eta_c(1S)) = 0.0127 \pm 0.0036$. Where relevant, the error in this branching ratio is treated as a common systematic in computing averages.

³ Estimated using $B(\psi(2S) \rightarrow \gamma \eta_c(1S)) = 0.0028 \pm 0.0006$.

⁴ WU 06 reports $[\Gamma(\eta_c(1S) \rightarrow p\bar{p})/\Gamma_{\text{total}}] \times [B(B^+ \rightarrow \eta_c K^+)] = (1.42 \pm 0.11 \pm 0.16) \times 10^{-6}$ which we divide by our best value $B(B^+ \rightarrow \eta_c K^+) = (9.6 \pm 1.1) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

3096.93 ±0.09	502	⁵ ZHOLENTZ	80 REDE	e^+e^-
3097.0 ±1		⁶ BRANDELIK	79c DASP	e^+e^-

- ¹ From a sample of $\eta_c(1S)$ and J/ψ produced in b -hadron decays.
² Supersedes AULCHENKO 03.
³ Reanalysis of ZHOLENTZ 80 using new electron mass (COHEN 87) and radiative corrections (KURAEV 85).
⁴ Mass central value and systematic error recalculated by us according to Eq. (16) in ARMSTRONG 93B, using the value for the $\psi(2S)$ mass from AULCHENKO 03.
⁵ Superseded by ARTAMONOV 00.
⁶ From a simultaneous fit to e^+e^- , $\mu^+\mu^-$ and hadronic channels assuming $\Gamma(e^+e^-) = \Gamma(\mu^+\mu^-)$.

$J/\psi(1S)$ WIDTH

VALUE (keV)	EVTS	DOCUMENT ID	TECN	COMMENT
92.9± 2.8 OUR AVERAGE				Error includes scale factor of 1.1.
96.1± 3.2	13k	¹ ADAMS	06A CLEO	$e^+e^- \rightarrow \mu^+\mu^-\gamma$

BRANCHING RATIOS OF $\psi(2S)$ AND $\chi_{c0,1,2}$

Updated August 2015 by J.J. Hernández-Rey (IFIC, Valencia), S. Navas (University of Granada), and C. Patrignani (INFN, Bologna Univ.)

Since 2002, the treatment of the branching ratios of the $\psi(2S)$ and $\chi_{c0,1,2}$ has undergone an important restructuring.

When measuring a branching ratio experimentally, it is not always possible to normalize the number of events observed in the corresponding decay mode to the total number of particles produced. Therefore, the experimenters sometimes report the number of observed decays with respect to another decay mode of the same or another particle in the relevant decay chain. This is actually equivalent to measuring combinations of branching fractions of several decay modes.

To extract the branching ratio of a given decay mode, the collaborations use some previously reported measurements of the required branching ratios. However, the values are frequently taken from the *Review of Particle Physics* (RPP), which in turn uses the branching ratio reported by the experiment in the following edition, giving rise either to correlations or to plain vicious circles Ref. 1, Ref. 2 as discussed in more detail in earlier editions of this mini-review.

The way to avoid these dependencies and correlations is to extract the branching ratios through a fit that uses the truly measured combinations of branching fractions and partial widths. This fit, in fact, should involve decays from the four concerned particles, $\psi(2S)$, χ_{c0} , χ_{c1} , and χ_{c2} , and occasionally some combinations of branching ratios of more than one of them. This is what is done since the 2002 edition [3].

The PDG policy is to quote the results of the collaborations in a manner as close as possible to what appears in their original publications. However, in order to avoid the problems mentioned above, we had in some cases to work out the values originally measured, using the number of events and detection efficiencies given by the collaborations, or rescaling back the published results. The information was sometimes spread over several articles, and some articles referred to papers still unpublished, which in turn contained the relevant numbers in footnotes.

Even though the experimental collaborations are entitled to extract whatever branching ratios they consider appropriate by

using other published results, we would like to encourage them to also quote explicitly in their articles the actual quantities measured, so that they can be used directly in averages and fits of different experimental determinations.

To inform the reader how we computed some of the values used in this edition of RPP, we use footnotes to indicate the branching ratios actually given by the experiments and the quantities they use to derive them from the true combination of branching ratios actually measured.

None of the branching ratios of the $\chi_{c0,1,2}$ are measured independently of the $\psi(2S)$ radiative decays. We tried to identify those branching ratios which can be correlated in a non-trivial way, and although we cannot preclude the existence of other cases, we are confident that the most relevant correlations have already been removed. Nevertheless, correlations in the errors of different quantities measured by the same experiment have not been taken into account.

FIT INFORMATION

This is an overall fit to 4 total widths, 1 partial width, 25 combinations of partial widths, 10 branching ratios, and 80 combinations of branching ratios. Of the latter 57 involve decays of more than one particle.

The overall fit uses 239 measurements to determine 49 parameters and has a χ^2 of 341.3 for 190 degrees of freedom.

The relatively high χ^2 of the fit, 1.8 per d.o.f., can be traced back to a few specific discrepancies in the data. No scaling factors to fit uncertainties have been applied.

In the listing we provide the inter-particle correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the corresponding parameter x_i .

20.2±1.1±1.5	720±32	² BAI 98i	BES	$\psi(2S) \rightarrow \gamma\chi_{c0} \rightarrow \gamma\pi^+\pi^-$
¹ We have multiplied $\pi^0\pi^0$ measurement by 3 to obtain $\pi\pi$.				
² Calculated by us. The value for $B(\chi_{c0} \rightarrow \pi^+\pi^-)$ reported in BAI 98i is derived using $B(\psi' \rightarrow \gamma\chi_{c0}) = (9.3 \pm 0.8)\%$ and $B(\psi' \rightarrow J/\psi\pi^+\pi^-) = (32.4 \pm 2.6)\%$ [BAI 98D]. We have multiplied $\pi^+\pi^-$ measurement by 3/2 to obtain $\pi\pi$.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 240 measurements to determine 49 parameters. The overall fit has a $\chi^2 = 342.4$ for 191 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$.

¹ Recalculated by ANDREOTTI 05A, using the value of $\psi(2S)$ mass from AULCHENKO 03.

² Using mass of $\psi(2S)$ = 3686.0 MeV.

³ $J/\psi(1S)$ mass constrained to 3097 MeV.

⁴ Assuming $\psi(2S)$ mass = 3686 MeV and $J/\psi(1S)$ mass = 3097 MeV.

⁵ Mass value shifted by us by amount appropriate for $\psi(2S)$ mass = 3686 MeV and $J/\psi(1S)$ mass = 3097 MeV.

⁶ From a simultaneous fit to radiative and hadronic decay channels.

[a] For a narrow resonance in the range $2.2 < M(X) < 2.8$ GeV.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 240 measurements to determine 49 parameters. The overall fit has a $\chi^2 = 342.4$ for 191 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$.

$\psi(2S)$

$\psi(2S) \Gamma(i) \Gamma(e^+ e^-) / \Gamma(\text{total})$

This combination of a partial width with the partial width into $e^+ e^-$ and with the total width is obtained from the integrated cross section into channel(i) in the $e^+ e^-$ annihilation. We list only data that have not been used to determine the partial width $\Gamma(i)$ or the branching ratio $\Gamma(i)/\text{total}$.

$\Gamma(\text{hadrons}) \times \Gamma(e^+ e^-) / \Gamma(\text{total})$

⁷ Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the $\psi(3770)$, $\psi(4040)$, $\psi(4160)$, and $\psi(4415)$ resonances. Phase angle fixed in the fit to $\delta = 0^\circ$.

⁸ Interference between the resonant and non-resonant $D\bar{D}$ production not taken into account.

 $\psi(3770)$ DECAY MODES

In addition to the dominant decay mode to $D\bar{D}$, $\psi(3770)$ was found to decay into the final states containing the J/ψ (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to $\phi\eta$ only (ADAMS 06).

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 3 branching ratios uses 23 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 20.1$ for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.96 ± 0.07 OUR FIT	Error includes scale factor of 1.3.			
1.3 ± 0.2	RAPIDIS	77	LGW	e^+e^-
¹⁶ Neglecting interference.				
¹⁷ Obtained by comparing a measurement of the total cross section (corrected in BESSON 10) with that of $D\bar{D}$ reported by CLEO in DOBBS 07.				
¹⁸ Using $\sigma^{obs} = 7.07 \pm 0.58$ nb and neglecting interference.				
¹⁹ Not independent of ABLIKIM 08b.				
²⁰ From a measurement of $\sigma(e^+e^- \rightarrow D\bar{D})$ at $\sqrt{s} = 3773$ MeV, using the $\psi(3770)$ resonance parameters measured by ABLIKIM 06L.				
²¹ See ADLER 88c for older measurements of this quantity.				
²² Superseded by BONVICINI 14.

<1.4	90	36	ABLIKIM	13Q BES3 $e^+e^- \rightarrow \psi(3770)$					

23 Comparing cross sections at $\sqrt{s} = 3.773\text{ GeV}$ and $\sqrt{s} = 3.671\text{ GeV}$, neglecting interference, and using $\sigma(\psi(3770) \rightarrow D\bar{D}) = 6.39 \pm 0.20\text{ nb}$.

24 Assuming that interference effects between resonance and continuum can be neglected and using $\sigma^{obs}(e^+e^- \rightarrow \psi(3770)) = 7.15 \pm 0.38\text{ nb}$.

25 Data suggest possible destructive interference with continuum.

26 DRUZHININ 15 uses BABAR and CLEO data takitaking into account interference of the processes $e^+e^- \rightarrow K^+K^-$ and $e^+e^- \rightarrow K_S^0\bar{K}_L^0$.

27 Using $\sigma(e^+e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = (6.38 \pm 0.08^{+0.41}_{-0.30})\text{ nb}$ from BESSON 06 and $B(K_S^0 \rightarrow \pi^+\pi^-) = 0.6895 \pm 0.0014$.

28 Using $B(K_S^0 \rightarrow \pi^+\pi^-) = 0.6860 \pm 0.0027$.

29 Using $\sigma_{tot}(e^+e^- \rightarrow \psi(3770)) = 7.9 \pm 0.6\text{ nb}$ at the resonance.

30 Solution I of two equivalent solutions in a fit with a resonance interfering with continuum.

31 Solution II of two equivalent solutions in a fit with a resonance interfering with continuum.

32 Calculated by the authors using $\sigma(e^+e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = 6.36 \pm 0.08^{+0.41}_{-0.30}\text{ nb}$ from BESSON 10.

33 Solution I of two equivalent solutions in a fit with a resonance interfering with continuum.

34 Solution II of two equivalent solutions in a fit with a resonance interfering with continuum.

35 Using $\sigma^{obs} = 7.15 \pm 0.27 \pm 0.27\text{ nb}$ and neglecting interference.

36 Assuming that interference effects between resonance and continuum can be neglected.

- ³⁷ This limit is equivalent to $(0.25 \pm 0.21 \pm 0.18) \times 10^{-3}$ branching fraction value.
- ³⁸ Uses $B(\psi(2S) \rightarrow \gamma\chi_{c2}) = 9.22 \pm 0.11 \pm 0.46\%$ from ATHAR 04, $\psi(2S)$ mass and width from PDG 04, and $\Gamma_{ee}(\psi(2S)) = 2.54 \pm 0.03 \pm 0.11$ keV from ADAM 06.
- ³⁹ Using $\Gamma_{ee}(\psi(2S)) = (2.54 \pm 0.03 \pm 0.11)$ keV from ADAM 06 and taking $\sigma(e^+e^- \rightarrow D\bar{D})$ from HE 05 for $\sigma(e^+e^- \rightarrow \psi(3770))$.
- ⁴⁰ ABLIKIM 16B reports $(1.94 \pm 0.42 \pm 0.64) \times 10^{-3}$ from a measurement of $[\Gamma(\psi(3770) \rightarrow \gamma\chi_{c1})/\Gamma_{\text{total}}] / [B(\psi(2S) \rightarrow \gamma\chi_{c1}(1P))]$ assuming $B(\psi(2S) \rightarrow \gamma\chi_{c1}(1P)) = (9.55 \pm 0.31) \times 10^{-2}$.
- ⁴¹ ABLIKIM 14H reports $[\Gamma(\psi(3770) \rightarrow \gamma\chi_{c1})/\Gamma_{\text{total}}] \times [B(\chi_{c1}(1P) \rightarrow K_S^0 K^\pm \pi^\mp)] = (8.51 \pm 2.39 \pm 1.42) \times 10^{-6}$ which we divide by our best value $B(\chi_{c1}(1P) \rightarrow K_S^0 K^\pm \pi^\mp) = 0.00356 \pm 0.00030$. Our first error is their experiment's error and our second error is the systematic error from using our best value. We have calculated the best value of $B(\chi_{c1}(1P) \rightarrow K_S^0 K^\pm \pi^\mp)$ as $1/2$ of $B(\chi_{c1}(1P) \rightarrow \bar{K}^0 K^+ \pi^- + \text{c.c.}) = (7.1 \pm 0.6) \times 10^{-3}$.
- ⁴² Averages the two measurements from COAN 06A and BRIERE 06.
- ⁴³ Uses $B(\psi(2S) \rightarrow \gamma\chi_{c1}) = 9.07 \pm 0.11 \pm 0.54\%$ from ATHAR 04, $\psi(2S)$ mass and width from PDG 04, and $\Gamma_{ee}(\psi(2S)) = 2.54 \pm 0.03 \pm 0.11$ keV from ADAM 06.
- ⁴⁴ Using $B(\psi(3770) \rightarrow J/\psi\pi^+\pi^-) = (1.89 \pm 0.20 \pm 0.20) \times 10^{-3}$ from ADAM 06.
- ⁴⁵ ABLIKIM 16B reports $(6.88 \pm 0.28 \pm 0.67) \times 10^{-3}$ from a measurement of $[\Gamma(\psi(3770) \rightarrow \gamma\chi_{c0})/\Gamma_{\text{total}}] / [B(\psi(2S) \rightarrow \gamma\chi_{c0}(1P))]$ assuming $B(\psi(2S) \rightarrow \gamma\chi_{c0}(1P)) = (9.99 \pm 0.27) \times 10^{-2}$.

⁴⁶ Not independent of other results in BRIERE 06.

⁴⁷ ABLIKIM 14H reports $[\Gamma(\psi(3770) \rightarrow \gamma\eta_c)/\Gamma_{\text{total}}] \times [B(\eta_c(1S) \rightarrow K_S^0 K^\pm \pi^\mp)] < 16 \times 10^{-6}$ which we divide by our best value $B(\eta_c(1S) \rightarrow K_S^0 K^\pm \pi^\mp) = 2.43 \times 10^{-2}$. We have calculated the best value of $B(\eta_c(1S) \rightarrow K_S^0 K^\pm \pi^\mp)$ as $1/3$ of $B(\eta_c(1S) \rightarrow K\bar{K}\pi) = 7.3 \times 10^{-2}$.

⁴⁸ ABLIKIM 14H reports $[\Gamma(\psi(3770) \rightarrow \gamma\eta_c(2S))/\Gamma_{\text{total}}] \times [B(\eta_c(2S) \rightarrow K_S^0 K^\pm \pi^\mp)] < 5.6 \times 10^{-6}$ which we divide by our best value $B(\eta_c(2S) \rightarrow K_S^0 K^\pm \pi^\mp) = 6 \times 10^{-3}$. We have calculated the best value of $B(\eta_c(2S) \rightarrow K_S^0 K^\pm \pi^\mp)$ as $1/3$ of $B(\eta_c(2S) \rightarrow K\bar{K}\pi) = 1.9 \times 10^{-2}$.

⁴⁹ Assuming maximal destructive interference between $\psi(3770)$ and continuum sources.

$\psi(3823)$
was $X(3823)$.

$I_G(J^{PC}) = ?(2^{-}-)$
 J, P need confirmation.

Seen by BHARDWAJ 13 in $B \rightarrow \chi_{c1} \gamma K$ and ABLIKIM 15S in $e^+e^- \rightarrow \pi^+\pi^-\gamma\chi_{c1}$ decays as a narrow peak in the invariant mass distribution of the $\chi_{c1} \gamma$ system. Properties consistent with the $\psi_2(1^3D_2) c\bar{c}$ state.

$\psi(3823)$ MASS

VALUE (MeV)	CL%	DOCUMENT ID	TECN	COMMENT
3822.2 ± 1.2 OUR AVERAGE				
3821.7 $\pm 1.3 \pm 0.7$	19 ± 5	¹ ABLIKIM	15S BES3	$e^+e^- \rightarrow \pi^+\pi^-\chi_{c1} \gamma$
3823.1 $\pm 1.8 \pm 0.7$	33 ± 10	² BHARDWAJ	13 BELL	$B \rightarrow \chi_{c1} \gamma K$

- ¹ From a simultaneous unbinned maximum likelihood fit of $e^+e^- \rightarrow \pi^+\pi^-\chi_{c1} \gamma$ data (the $\pi^+\pi^-$ recoil mass) taken at \sqrt{s} values of 4.23, 4.26, 4.36, 4.42, and 4.60 GeV to simulated events including both $\psi(2S) \rightarrow \chi_{c1} \gamma$ and $\psi(3823) \rightarrow \chi_{c1} \gamma$ together, with floating mass scale offset for $\psi(2S)$, floating $\psi(3823)$ mass, and zero $\psi(3823)$ width, resulting in a significance of 5.9 σ when including systematic uncertainties.
- ² From a simultaneous fit to $B^\pm \rightarrow (\chi_{c1} \gamma) K^\pm$ and $B^0 \rightarrow (\chi_{c1} \gamma) K_S^0$ with significance 4.0 σ including systematics. Corrected for the measured $\psi(2S)$ mass using $B \rightarrow \psi(2S) K \rightarrow (\gamma\chi_{c1}) K$ decays.

X(3872)

$$I^G(J^{PC}) = 0^+(1^{++})$$

First observed by CHOI 03 in $B \rightarrow K\pi^+\pi^-J/\psi(1S)$ decays as a narrow peak in the invariant mass distribution of the $\pi^+\pi^-J/\psi(1S)$ final state. Isovector hypothesis excluded by AUBERT 05B and CHOI 11.

AAIJ 13Q perform a full five-dimensional amplitude analysis of the angular correlations between the decay products in $B^+ \rightarrow X(3872)K^+$ decays, where $X(3872) \rightarrow J/\psi\pi^+\pi^-$ and $J/\psi \rightarrow \mu^+\mu^-$, which unambiguously gives the $J^{PC} = 1^{++}$ assignment under the assumption that the $\pi^+\pi^-$ and J/ψ are in an S -wave. AAIJ 15AO extend this analysis with more data to limit D -wave contributions to $< 4\%$ at 95% CL.

See our note on “Developments in Heavy Quarkonium Spectroscopy”.

X(3900)

$I^G(J^{PC}) = 1^+(1^{+-})$

Charged X(3900) seen as a peak in the invariant mass distribution of the $J/\psi\pi^\pm$ system by BES III (ABLIKIM 13T) in $e^+e^- \rightarrow \pi^+\pi^- J/\psi$ at c.m. energy of 4.26 GeV and by radiative return from e^+e^- collisions at \sqrt{s} from 9.46 to 10.86 GeV at Belle (LIU 13B). Angular analysis of ABLIKIM 14A and ABLIKIM 15AC favor the $J^P = 1^+$ assignment. Neutral X(3900) seen in the $J/\psi\pi^0$ invariant mass distribution in $e^+e^- \rightarrow \pi^0\pi^0 J/\psi$ at c.m. energies of 4.23, 4.26, and 4.36 GeV by BES III (ABLIKIM 15U) and at 4.17 GeV by XIAO 13A. Peaks in $(D\overline{D}^*)^{0,\pm}$ reported by BES III (ABLIKIM 14A, ABLIKIM 15AB) are assumed to be related.

X(3915)

was $\chi_{c0}(3915)$

$$J^G(J^{PC}) = 0^+(0 \text{ or } 2^{++})$$

The experimental analysis prefers $J^{PC} = 0^{++}$. However, a re-analysis presented in ZHOU 15C shows that if helicity-2 dominance assumption is abandoned and a sizable helicity-0 component is allowed, a $J^{PC} = 2^{++}$ assignment is possible.

Meson Particle Listings

X(4020), $\psi(4040)$

X(4020)

$$I(J^P) = 1(?)^?$$

Charged X(4020) seen by ABLIKIM 13X from $e^+e^- \rightarrow \pi^+\pi^-h_c(1P)$ at c.m. energy from 3.90 to 4.42 GeV as a peak in the invariant mass distribution of the $\pi^\pm h_c(1P)$ system, and by ABLIKIM 14B from $e^+e^- \rightarrow (D^*\bar{D}^*)^\pm\pi^\mp$ events in $(D^*\bar{D}^*)^\pm$ mass. A neutral X(4020) seen by ABLIKIM 14P at three c.m. energies in the same range in $e^+e^- \rightarrow \pi^0\pi^0h_c(1P)$ as a peak in the larger of the two masses recoiling against a π^0 . ABLIKIM 15AA observes a 5.9σ signal in $(D^*\bar{D}^*)^0$ in $e^+e^- \rightarrow (D^*\bar{D}^*)^0\pi^0$ events using collisions at two c.m. energies. Production rates and mass values support grouping neutral and charged X(4020) together as manifestations of a single $I = 1$ particle.

⁵ Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the $\psi(3770)$, $\psi(4040)$, $\psi(4160)$, and $\psi(4415)$ resonances. Phase angle fixed in the fit to $\delta = (130 \pm 46)^\circ$.

⁶ Reanalysis of data presented in BAI 00 and BAI 02c. From a global fit over the center-of-mass energy 3.8–4.8 GeV covering the $\psi(4040)$, $\psi(4160)$ and $\psi(4415)$ resonances and including interference effects.

⁷ From a fit to Crystal Ball (OSTERHELD 86) data.

⁸ From a fit to BES (BAI 02c) data.

$\psi(4040)$ DECAY MODES

Due to the complexity of the $c\bar{c}$ threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective \sqrt{s} near this particle's central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in \sqrt{s} or absence thereof. See mode listing(s) for details and references.

$\psi(4160)$ DECAY MODES			
Due to the complexity of the $c\bar{c}$ threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective \sqrt{s} near this particle’s central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in \sqrt{s} or absence thereof. See mode listing(s) for details and references.

$\psi(4415)$ DECAY MODES

Due to the complexity of the $c\bar{c}$ threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective \sqrt{s} near this particle’s central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in \sqrt{s} or absence thereof. See mode listing(s) for details and references.

$b\bar{b}$ MESONS
THE BOTTOMONIUM SYSTEM

The level scheme of the $b\bar{b}$ states showing experimentally established states with solid lines. Singlet states are called η_b and h_b , triplet states Y and χ_{bJ} . In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. *E.g.*, $h_b(2P)$ means 2^1P_1 with $n = 2$, $L = 1$, $S = 0$, $J = 1$, $PC = +-$. The figure shows observed hadronic transitions. The single photon transitions $Y(nS) \rightarrow \gamma\eta_b(mS)$, $Y(nS) \rightarrow \gamma\chi_{bJ}(mP)$, and $\chi_{bJ}(nP) \rightarrow \gamma Y(mS)$ are omitted for clarity.

WIDTH DETERMINATIONS OF THE Y STATES

As is the case for the $J/\psi(1S)$ and $\psi(2S)$, the full widths of the $b\bar{b}$ states $Y(1S)$, $Y(2S)$, and $Y(3S)$ are not directly measurable, since they are much narrower than the energy resolution of the e^+e^- storage rings where these states are produced. The common indirect method to determine Γ starts from

$$\Gamma = \Gamma_{\ell\ell}/B_{\ell\ell} \quad (1)$$

where $\Gamma_{\ell\ell}$ is one leptonic partial width and $B_{\ell\ell}$ is the corresponding branching fraction ($\ell = e, \mu$, or τ). One then assumes e - μ - τ universality and uses

$$\begin{aligned} \Gamma_{\ell\ell} &= \Gamma_{ee} \\ B_{\ell\ell} &= \text{average of } B_{ee}, B_{\mu\mu}, \text{ and } B_{\tau\tau} \end{aligned} \quad (2)$$

The electronic partial width Γ_{ee} is also not directly measurable at e^+e^- storage rings, only in the combination $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$, where Γ_{had} is the hadronic partial width and

$$\Gamma_{\text{had}} + 3\Gamma_{ee} = \Gamma \quad (3)$$

This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\begin{aligned} \int_{\text{resonance}} \sigma(e^+e^- \rightarrow Y \rightarrow \text{hadrons}) dE \\ = \frac{6\pi^2 \Gamma_{ee}\Gamma_{\text{had}}}{M^2 \Gamma} C_r = \frac{6\pi^2 \Gamma_{ee}^{(0)}\Gamma_{\text{had}}}{M^2 \Gamma} C_r^{(0)} \end{aligned} \quad (4)$$

where M is the Y mass, and C_r and $C_r^{(0)}$ are radiative correction factors. C_r is used for obtaining Γ_{ee} as defined in Eq. (1), and contains corrections from all orders of QED for describing $(b\bar{b}) \rightarrow e^+e^-$. The lowest order QED value $\Gamma_{ee}^{(0)}$, relevant for comparison with potential-model calculations, is defined by the lowest order QED graph (Born term) alone, and is about 7% lower than Γ_{ee} .

The Listings give experimental results on B_{ee} , $B_{\mu\mu}$, $B_{\tau\tau}$, and $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$. The entries of the last quantity have been re-evaluated consistently using the correction procedure of KU-RAEV 85. The partial width Γ_{ee} is obtained from the average values for $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$ and $B_{\ell\ell}$ using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{\text{had}}}{\Gamma(1 - 3B_{\ell\ell})} \quad (5)$$

See key on page 601

Meson Particle Listings

Bottomonium, $\eta_b(1S)$

The total width Γ is then obtained from Eq. (1). We do not list Γ_{ee} and Γ values of individual experiments. The Γ_{ee} values in the Meson Summary Table are also those defined in Eq. (1).

$\eta_b(1S)$	$I^G(J^{PC}) = 0^+(0^{-+})$
Quantum numbers shown are quark-model predictions. Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$.

3.4 ± 0.4 ± 0.4	GILES	83	CLEO	$e^+ e^- \rightarrow \tau^+ \tau^-$

⁸ BESSON 07 reports $[\Gamma(\Upsilon(1S) \rightarrow \tau^+ \tau^-) / \Gamma_{\text{total}}] / [B(\Upsilon(1S) \rightarrow \mu^+ \mu^-)] = 1.02 \pm 0.02 \pm 0.05$ which we multiply by our best value $B(\Upsilon(1S) \rightarrow \mu^+ \mu^-) = (2.48 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

⁹ Using $B(\Upsilon(1S) \rightarrow ee) = B(\Upsilon(1S) \rightarrow \mu\mu) = 0.0256$; not used for width evaluations.

²⁵ BESSON 11 reports $(4.0 \pm 1.3 \pm 0.6) \times 10^{-5}$ from a measurement of $[\Gamma(\Upsilon(1S) \rightarrow \gamma f'_2(1525))/\Gamma_{\text{total}}] \times [B(f'_2(1525) \rightarrow K\bar{K})]$ assuming $B(f'_2(1525) \rightarrow K\bar{K}) = (88.8 \pm 3.1) \times 10^{-2}$, which we rescale to our best value $B(f'_2(1525) \rightarrow K\bar{K}) = (88.7 \pm 2.2) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. The result also assumes $B(K_S^0 \rightarrow \pi^+\pi^-) = (69.20 \pm 0.05)\%$ and $B(f'_2(1525) \rightarrow K\bar{K}) = 4 B(f'_2(1525) \rightarrow K_S^0 K_S^0)$.					
²⁶ Assuming $B(f'_2(1525) \rightarrow K\bar{K}) = 0.71$.

$\chi_{b0}(1P)$

$$J^G(J^{PC}) = 0^+(0^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b1}(1P)$ $I^G(J^{PC}) = 0^+(1^+ +)$ J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$. $J = 1$ from SKWARNICKI 87.

$\chi_{b2}(1P)$

$$I^G(J^{PC}) = 0^+(2^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$. $J = 2$ from SKWARNICKI 87.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 11.8$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i\delta x_j\rangle/(\delta x_i\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Upsilon(1D)$

$$I^G(J^{PC}) = 0^-(2^--)$$

First observed by BONVICINI 04 in the decay to $\gamma\gamma \Upsilon(1S)$ and confirmed by DEL-AMO-SANCHEZ 10R in the decay to $\pi^+ \pi^- \Upsilon(1S)$. Data consistent with $J^P = 2^-$. The states with $J = 1$ and 3 also possibly seen, but need confirmation.

BONVICINI 04	PR D70 032001	G. Bonvicini et al.	(CLEO Collab.)

$$\chi_{b0}(2P) \quad J^G(J^{PC}) = 0^+(0^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b1}(2P)$

$J^G(J^{PC}) = 0^+(1^+ +)$
 J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b2}(2P)$

$$J^G(J^{PC}) = 0^+(2^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

 $\Upsilon(4S)$ WEIGHTED AVERAGE
0.272±0.029 (Error scaled by 1.5) $\Upsilon(4S)$ BRANCHING RATIOS $B\bar{B}$ DECAYS

The ratio of branching fraction to charged and neutral B mesons is often derived assuming isospin invariance in the decays, and relies on the knowledge of the B^+/B^0 lifetime ratio. "OUR EVALUATION" is obtained based on averages of rescaled data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account the common dependence of the measurement on the value of the lifetime ratio.

$X(10610)^{\pm}$

$I^G(J^P) = 1^+(1^+)$

Observed by BONDAR 12 in $\Upsilon(5S)$ decays to $\Upsilon(nS)\pi^+\pi^-$ (n = 1, 2, 3) and $h_b(mP)\pi^+\pi^-$ (m = 1, 2). $J^P = 1^+$ is favored from angular analyses. Isospin = 1 is favored due to observation by KROKOVNY 13 of a corresponding neutral state produced in $\Upsilon(10860) \rightarrow \Upsilon(2S)/\Upsilon(3S)\pi^0\pi^0$ decays at a consistent mass.

$X(10610)^0$

$J^G(J^P) = 1^+(1^+)$

Observed by KROKOVNY 13 in $\Upsilon(10860) \rightarrow \Upsilon(nS)\pi^0\pi^0$ ($n=2,3$). Isospin 1 is favored from the proximity in mass to $X(10610)^{\pm}$ and their similarity of observed decay modes and cross sections. $J^P = 1^+$ is favored from angular analysis of $X(10610)^{\pm}$ decays by BONDAR 12.

- ¹ From a simultaneous fit to the $\Upsilon(nS) \pi^+ \pi^-$, $n = 1, 2, 3$ cross sections at 25 energy points within $\sqrt{s} = 10.6\text{--}11.05$ GeV to a pair of interfering Breit-Wigner amplitudes modified by phase space factors, with fourteen resonance parameters (a mass, width, and three amplitudes for each of $\Upsilon(10860)$ and $\Upsilon(11020)$, a single universal relative phase, and three decoherence coefficients, one for each n). Continuum contributions were measured (and therefore fixed) to be zero.
- ² From a fit to the total hadronic cross sections measured at 60 energy points within $\sqrt{s} = 10.82\text{--}11.05$ GeV to a pair of interfering Breit-Wigner amplitudes and two floating continuum amplitudes with $1/\sqrt{s}$ dependence, one coherent with the resonances and one incoherent, with six resonance parameters (a mass, width, and an amplitude for each of $\Upsilon(10860)$ and $\Upsilon(11020)$, one relative phase, and one decoherence coefficient).
- ³ Not including uncertain and potentially large systematic errors due to assumed continuum amplitude $1/\sqrt{s}$ dependence and related interference contributions.
- ⁴ In a model where a flat non-resonant $b\bar{b}$ -continuum is incoherently added to a second flat component interfering with two Breit-Wigner resonances. Systematic uncertainties not estimated.
- ⁵ The parameters of the $\Upsilon(11020)$ are fixed to those in AUBERT 09E.
- ⁶ In a model where a flat nonresonant $\Upsilon(1S, 2S, 3S) \pi^+ \pi^-$ continuum interferes with a single Breit-Wigner resonance.
- ⁷ In a model where a non-resonant $b\bar{b}$ -continuum represented by a threshold function at $\sqrt{s}=2m_B$ is incoherently added to a flat component interfering with two Breit-Wigner resonances. Not independent of other AUBERT 09E results. Systematic uncertainties not estimated.
- ⁸ Assuming four Gaussians with radiative tails and a single step in R .
- ⁹ In a coupled-channel model with three resonances and a smooth step in R .

¹⁹ Not independent of DRUTSKOY 10 values for $\Upsilon(5S) \rightarrow B^{\pm,0} \text{ anything}$.
²⁰ Using measurements or limits from AQUINES 06.
²¹ Assuming isospin conservation.
²² Supersedes DRUTSKOY 07.
²³ Supersedes ARTUSO 05B. Combining inclusive ϕ , D_s , and B measurements. Using $B(D_s^+ \rightarrow \phi\pi^+) = 4.4 \pm 0.6\%$ from PDG 06.
²⁴ Using $B(D_s^+ \rightarrow \phi\pi^+) = (4.4 \pm 0.6)\%$ from PDG 06.
²⁵ Uses a model-dependent estimate $B(B_s \rightarrow D_s X) = (92 \pm 11)\%$.
²⁶ Supersedes LOUVOT 09.
²⁷ With $N(B_s^{(*)}\bar{B}_s^{(*)}) = (7.11 \pm 1.30) \times 10^6$.
²⁸ The ratios $N(B_s^*\bar{B}_s^{(*)})/N(B_s^{(*)}\bar{B}_s^{(*)})$ and $N(B_s^*\bar{B}_s^0)/N(B_s^{(*)}\bar{B}_s^{(*)})$ are measured with a correlation coefficient of -0.72 .
²⁹ From a measurement of $\sigma(e^+e^- \rightarrow B_s^*\bar{B}_s^*)/\sigma(e^+e^- \rightarrow B_s^{(*)}\bar{B}_s^{(*)})$ at $\sqrt{s} = 10.86$ GeV.
³⁰ Assuming that the observed events are solely due to the $\Upsilon(5S)$ resonance.
³¹ Assuming that all the $b\bar{b}$ events are from $\Upsilon(5S)$ resonance decays and using $\sigma(e^+e^- \rightarrow b\bar{b}) = 0.340 \pm 0.016$ nb from ESEN 13. Correlated with other results from HE 14.
³² Accounting for correlated systematics.
³³ Assuming that all the $b\bar{b}$ events are from $\Upsilon(5S)$ resonance decays and using $\sigma(e^+e^- \rightarrow b\bar{b}) = 0.340 \pm 0.016$ nb from ESEN 13. Correlated with other results from HE 14. For a state X_b with mass between 10.55 GeV/c² and 10.65 GeV/c², the obtained 90% upper limit as a function of m_{X_b} varies from 2.6×10^{-5} to 3.8×10^{-5} .
³⁴ ARTUSO 05B reports $[\Gamma(\Upsilon(10860) \rightarrow D_s \text{ anything} + \text{c.c.})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)] = 0.0198 \pm 0.0019 \pm 0.0038$ which we divide by our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

Meson Particle Listings

Non- $q\bar{q}$ Candidates

NON- $q\bar{q}$ CANDIDATES

NON- $q\bar{q}$ MESONS

Revised August 2015 by C. Amsler (University of Bern and Stefan Meyer Institute for Subatomic Physics, Vienna) and C. Hanhart (Forschungszentrum Jülich).

The constituent quark model describes the observed meson spectrum as bound $q\bar{q}$ states grouped into SU(N) flavor multiplets (see our review on the ‘Quark Model’ in this issue of the *Review*). However, the self-coupling of gluons in QCD suggests that additional mesons made of bound gluons (glueballs), or $q\bar{q}$ -pairs with an excited gluon (hybrids), may exist. Multiquark color singlet states such as $qq\bar{q}\bar{q}$ (tetraquarks as compact diquark-antidiquark systems and ‘molecular’ bound states of two mesons) or $qqq\bar{q}\bar{q}\bar{q}$ (six-quark and ‘baryonium’ bound states of two baryons) have also been predicted. For a more detailed discussion on exotic mesons we refer to [1,2].

In recent years experimental evidence for states beyond the quark model has accumulated in the heavy quark sector. We therefore split this mini-review into three parts discussing separately light systems, heavy-light systems and heavy-heavy systems.

1. Light systems

1.1. Glueball candidates

Among the signatures naively expected for glueballs are (i) no free space in $q\bar{q}$ nonets, (ii) enhanced production in gluon-rich channels such as central production and radiative $J/\psi(1S)$ decay, (iii) decay branching fractions incompatible with SU(N) predictions for $q\bar{q}$ states, and (iv) reduced $\gamma\gamma$ couplings. However, mixing effects with isoscalar $q\bar{q}$ mesons [3–10] and decay form factors [11] obscure these simple signatures.

Lattice calculations, QCD sum rules, flux tube, and constituent glue models agree that the lightest glueballs have quantum numbers $J^{PC} = 0^{++}$ and 2^{++} . Lattice calculations predict for the ground state (a 0^{++} glueball) a mass around 1600 – 1700 MeV [8,12–14] with an uncertainty of about 100 MeV, while the first excited state (2^{++}) has a mass of about 2300 MeV. Hence, the low-mass glueballs lie in the same mass region as ordinary isoscalar $q\bar{q}$ states, in the mass range of the $1^3P_0(0^{++})$, $2^3P_2(2^{++})$, $3^3P_2(2^{++})$, and $1^3F_2(2^{++})$ $q\bar{q}$ states. The 0^{-+} state and exotic glueballs (with non- $q\bar{q}$ quantum numbers such as 0^{--} , 0^{+-} , 1^{-+} , 2^{-+} , etc.) are expected above 2 GeV [14]. The lattice calculations were performed so far in the quenched approximation. Thus neither quark loops nor mixing with conventional mesons were included, although quenching effects seem to be small [15]. For a recent comparison between quenched and unquenched lattice studies see [16].

However, one expects that glueballs will mix with nearby $q\bar{q}$ states of the same quantum numbers. The presence of a glueball mixed with $q\bar{q}$ would lead to a supernumerary isoscalar

state in the SU(3) classification of $q\bar{q}$ mesons. A lattice study in full QCD (performed at unphysical quark masses corresponding to a pion mass of 400 MeV) did not identify any state with sizable overlap with pure gluonic sources [17].

In the following we focus on glueball candidates in the scalar sector. For the 2^{++} sector we refer to the section on non- $q\bar{q}$ mesons in the 2006 issue of this *Review* [18], and for the 0^{-+} glueball to the note on ‘The Pseudoscalar and Pseudovector Mesons in the 1400 MeV Region’ in the *Meson Listings*.

Five isoscalar resonances are well established: the very broad $f_0(500)$ (or σ), the $f_0(980)$, the broad $f_0(1370)$, and the comparatively narrow $f_0(1500)$ and $f_0(1710)$, see the note on ‘Scalar Mesons below 2 GeV’ in the *Meson Listings*, and also [19]. The $f_0(1370)$ and $f_0(1500)$ decay mostly into pions (2π and 4π) while the $f_0(1710)$ decays mainly into $K\bar{K}$ final states. Naively, this suggests an $n\bar{n}$ ($= u\bar{u} + d\bar{d}$) structure for the $f_0(1370)$ and $f_0(1500)$, and $s\bar{s}$ for the $f_0(1710)$. The latter is not observed in $p\bar{p}$ annihilation [20], as expected from the OZI suppression for an $s\bar{s}$ state.

In $\gamma\gamma$ collisions leading to $K_S K_S$ [21] and $K^+ K^-$ [22] a spin-0 signal is observed at the $f_0(1710)$ mass (together with a dominant spin-2 component), while the $f_0(1500)$ is not observed in $\gamma\gamma \rightarrow K\bar{K}$ nor $\pi^+\pi^-$ [23]. The $f_0(1500)$ is also not observed by Belle in $\gamma\gamma \rightarrow \pi^0\pi^0$, although a shoulder is seen which could also be due to the $f_0(1370)$ [24]. The absence of a signal in the $\pi\pi$ channel in $\gamma\gamma$ collisions does not favor an $\bar{n}n$ interpretation for the $f_0(1500)$. The upper limit from $\pi^+\pi^-$ excludes a large $n\bar{n}$ content, and hence points to a mainly $s\bar{s}$ content [25]. This is in contradiction with the small $K\bar{K}$ decay branching ratio of the $f_0(1500)$ [26–28]. Hence, the $f_0(1500)$ is hard to accommodate as a $q\bar{q}$ state. This state could be mainly glue due its absence of 2γ -coupling, while the $f_0(1710)$ coupling to 2γ would be compatible with an $s\bar{s}$ state. Indeed, Belle finds that in $\gamma\gamma \rightarrow K_S K_S$ collisions the 1500 MeV region is dominated by the $f'_2(1525)$. The $f_0(1710)$ is also observed but its production \times decay rate is too large for a glueball [29]. However, the 2γ -couplings are sensitive to glue mixing with $q\bar{q}$ [30].

Since the $f_0(1370)$ does not couple strongly to $s\bar{s}$ [28], the $f_0(1370)$ or $f_0(1500)$ appear to be supernumerary. The narrow width of the $f_0(1500)$, and its enhanced production at low transverse momentum transfer in central collisions [31–33] also favor the $f_0(1500)$ to be non- $q\bar{q}$. In [3] the ground state scalar nonet is made of the $a_0(1450)$, $f_0(1370)$, $K_0^*(1430)$, and $f_0(1710)$. The isoscalars $f_0(1370)$ and $f_0(1710)$ contain a small fraction of glue, while the $f_0(1500)$ is mostly gluonic. The light scalars $f_0(500)$, $f_0(980)$, $a_0(980)$, and $\kappa(800)$ are four-quark states or two-meson resonances (see [1] for a review). In the mixing scheme of [30], which uses central production data from WA102 and the recent hadronic J/ψ decay data from BES [34,35], glue is shared between the $f_0(1370)$, $f_0(1500)$ and $f_0(1710)$. The $f_0(1370)$ is mainly $n\bar{n}$, the $f_0(1500)$ mainly glue and the $f_0(1710)$ dominantly $s\bar{s}$. This agrees with previous analyses [3,9], but, as already pointed out, alternative schemes

have been proposed, see, e.g. [8,36]. In particular, for a scalar glueball the two-gluon coupling to $n\bar{n}$ appears to be suppressed by chiral symmetry [37] and therefore $K\bar{K}$ decay could be enhanced. It was argued that chiral symmetry constraints in a multichannel analysis imply that the $f_0(1710)$ is an unmixed scalar glueball [38], a view that is challenged [39].

The contribution of $f_0(1500)$ production in (the supposedly gluon rich) radiative J/ψ decay is not well known. The $f_0(1500)$ is observed by BESII in $J/\psi \rightarrow \gamma\pi\pi$ [40] and by BESIII in $J/\psi \rightarrow \gamma\eta\eta$ [41] with a much smaller rate than for the $f_0(1710)$, which speaks against a glueball interpretation for the former. However, the mass found by BES is significantly lower than the expected value. The overlap with the $f_0(1370)$ and $f'_2(1525)$ and the statistically limited data sample prevent a proper K -matrix analysis to be performed. Hence more data are needed in radiative J/ψ decay and in $\gamma\gamma$ collisions to clarify the spectrum of scalar mesons.

The Dalitz plots of $B^\pm \rightarrow \pi^\pm\pi^\pm\pi^\mp$ have been studied by BaBar [42]. A broad 2π signal is observed around 1400 MeV which is attributed to the $f_0(1370)$, but could also be due to the $f_0(1500)$. In $B^\pm \rightarrow K^\pm K^\pm K^\mp$ both BaBar [43] and Belle [44] observe a strong spin-0 activity in $K\bar{K}$ around 1550 MeV. B^0 decay into $J/\psi X$ filters out the $d\bar{d}$ content of X while B_s^0 decay selects its $s\bar{s}$ component. B decay into $J/\psi X$ may therefore be the ideal environment to determine the flavor content of neutral mesons [45], or to distinguish $q\bar{q}$ from tetraquark states [46]. LHCb has analyzed \bar{B}^0 decay into $J/\psi\pi^+\pi^-$ [47]. The fit to the $\pi\pi$ mass spectrum above ~ 1.2 GeV does not show any significant scalar component. However, the data analysis has been challenged [48]. For $\bar{B}_s^0 \rightarrow J/\psi\pi^+\pi^-$ a scalar contribution from the $f_0(1370)$ [49] or the $f_0(1500)$ [50] is required in the 1400–1500 MeV region.

1.2. Tetraquark candidates and molecular bound states

The $a_0(980)$ and $f_0(980)$ could be tetraquark states [51–53] or $K\bar{K}$ molecular states [54–56] due to their strong affinity for $K\bar{K}$, in spite of their masses being very close to threshold. For $q\bar{q}$ states, the expected $\gamma\gamma$ widths [57,58] are not significantly larger than for molecular states [57,59], both predictions being consistent with data. Radiative decays of the $\phi(1020)$ into $a_0(980)$ and $f_0(980)$ were claimed to enable disentangling compact from molecular structures. Interpreting the data from DAPHNE [60,61] and VEPP - 2M [62,63] along the lines of [64,65] seems to favor these mesons to be tetraquark states. In [66] they are made of a four-quark core and a virtual $K\bar{K}$ cloud at the periphery. This is challenged in [67] showing that ϕ radiative decay data are consistent with a molecular structure of the light scalars. The $f_0(980)$ is strongly produced in D_s^+ decay [68]. This points to a large $s\bar{s}$ component, assuming Cabibbo favored $c \rightarrow s$ decay. However, the mainly $n\bar{n}$ $f_0(1370)$ is also strongly produced in D_s^+ decay, indicating that other graphs must contribute [69]. On the other hand, the contributions

from the $f_0(500)$ and $f_0(980)$ in the decay $\bar{B}^0 \rightarrow J/\psi\pi^+\pi^-$ seem to exclude a tetraquark structure for these states [47], while the corresponding ones in $\bar{B}_s^0 \rightarrow J/\psi\pi^+\pi^-$ are compatible with tetraquarks [50].

COMPASS reports a new 1^{++} isovector meson at 1414 MeV, decaying into $f_0(980)\pi$ [70]. The resonance is observed in diffractive dissociation $\pi^-p \rightarrow \pi^-(\pi^+\pi^-)p$. Traditionally, the 1^{++} ground state nonet is believed to contain the $a_1(1260)$, $f_1(1285)$ and $f_1(1420)$ (see the mini-review on ‘The Pseudoscalar and Pseudovector Mesons in the 1400 MeV Region’ in the *Meson Listings*). However, a molecular $K\bar{K}\pi$ structure has been proposed for the $f_1(1420)$ [71] in view of the proximity of the $K^*\bar{K}$ threshold. The new $a_1(1414)$ could then also be a molecular state, the isovector partner of the $f_1(1420)$.

1.3. Baryonia

Bound states of two nucleons have been predicted, but have remained elusive. The $f_2(1565)$ which is only observed in $\bar{p}p$ annihilation [72,73] is a good candidate for a 2^{++} $\bar{p}p$ bound state. Enhancements in the $\bar{p}p$ mass spectrum have also been reported below $\bar{p}p$ threshold, in $J/\psi \rightarrow \gamma\bar{p}p$ [74–76] and in $B^+ \rightarrow K^+\bar{p}p$, $B^0 \rightarrow K_S^0\bar{p}p$ [77,78] and $\bar{B}^0 \rightarrow D^0\bar{p}p$ [79]. This enhancement could be due to a 0^{-+} baryonium [80] but other explanations have been proposed, such as the dynamics of the fragmentation mechanism [78] or the attractive 1S_0 ($\bar{p}p$) wave [81–83].

The pronounced signal observed in $e^+e^- \rightarrow \Lambda_c^+\Lambda_c^-$ around $\sqrt{s} = 4.63$ GeV by Belle [84] was argued to be a strong evidence in favor of an interpretation of $Y(4660)$ as charmed baryonium [85]. However, this picture was challenged in [86].

1.4. Hybrid mesons

Hybrids may be viewed as $q\bar{q}$ mesons with a vibrating gluon flux tube. In contrast to glueballs, they can have isospin 0 or 1. The mass spectrum of hybrids with exotic (non- $q\bar{q}$) quantum numbers was predicted in [87], while [88] also deals with non-exotic quantum numbers. The ground state hybrids with quantum numbers (0^{-+} , 1^{-+} , 1^{--} , and 2^{-+}) are expected around 1.7 to 1.9 GeV. Lattice calculations predict that the hybrid with exotic quantum numbers 1^{-+} lies at a mass of 1.9 ± 0.2 GeV [89,90]. Most hybrids are expected to be rather broad, but some can be as narrow as 100 MeV [91]. They prefer to decay into a pair of S - and P -wave mesons. The lattice study in [17], based on full QCD with pion masses around 400 MeV, finds that several of the high-lying states observed in their spectrum show significant overlap with gluon rich source terms.

A $J^{PC} = 1^{-+}$ exotic meson, $\pi_1(1400)$, was reported in $\pi^-p \rightarrow \eta\pi^-p$ [92,93] and in $\pi^-p \rightarrow \eta\pi^0n$ [94]. It was observed as an interference between the angular momentum $L = 1$ and $L = 2$ $\eta\pi$ amplitudes, leading to a forward/backward asymmetry in the $\eta\pi$ angular distribution. This state has been reported earlier in π^-p reactions [95], but ambiguous solutions

Meson Particle Listings

Non- $q\bar{q}$ Candidates

in the partial wave analysis were pointed out in [96,97]. A resonating 1^{-+} contribution to the $\eta\pi$ P -wave is also required in the Dalitz plot analysis of $\bar{p}n$ annihilation into $\pi^-\pi^0\eta$ [98], and in $\bar{p}p$ annihilation into $\pi^0\pi^0\eta$ [99]. Mass and width are consistent with the results of Ref. [92].

Another 1^{-+} state, $\pi_1(1600)$, decaying into $\rho\pi$, was reported by COMPASS with 190 GeV pions hitting a lead target [100]. It was observed earlier in π^-p interactions in the decay modes $\eta'\pi$ [101], $f_1(1285)\pi$ [102], and $\omega\pi\pi$ [103], $b_1(1235)\pi$, but not $\eta\pi$ [104]. A strong enhancement in the 1^{-+} $\eta'\pi$ wave, compared to $\eta\pi$, was reported at this mass in [105]. Ref. [106] suggests that a Deck-generated $\eta\pi$ background from final state rescattering in $\pi_1(1600)$ decay could mimic $\pi_1(1400)$. However, this mechanism is absent in $\bar{p}p$ annihilation. The $\eta\pi\pi$ data require $\pi_1(1400)$ and cannot accommodate a state at 1600 MeV [107]. Finally, evidence for a $\pi_1(2015)$ has also been reported [102,103].

The flux tube model and the lattice concur to predict a hybrid mass of about 1.9 GeV while the $\pi_1(1400)$ and $\pi_1(1600)$ are lighter. As isovectors, $\pi_1(1400)$ and $\pi_1(1600)$ cannot be glueballs. The coupling to $\eta\pi$ of the former points to a four-quark state [108], while the strong $\eta'\pi$ coupling of the latter is favored for hybrid states [109,110]. The mass of $\pi_1(1600)$ is also not far below the lattice prediction.

Hybrid candidates with $J^{PC} = 0^{-+}$, 1^{--} , and 2^{-+} have also been reported. The $\pi(1800)$ decays mostly to a pair of S - and P -wave mesons [100,111], in line with expectations for 0^{-+} hybrid mesons. This meson is also somewhat narrow if interpreted as the second radial excitation of the pion. The evidence for 1^{--} hybrids required in e^+e^- annihilation and in τ decays has been discussed in Ref. [112]. A candidate for the 2^{-+} hybrid, the $\eta_2(1870)$, was reported in $\gamma\gamma$ interactions [113], in $\bar{p}p$ annihilation [114], and in central production [115]. The near degeneracy of $\eta_2(1645)$ and $\pi_2(1670)$ suggests ideal mixing in the 2^{-+} $q\bar{q}$ nonet, and hence, the second isoscalar should be mainly $s\bar{s}$. However, $\eta_2(1870)$ decays mainly to $a_2(1320)\pi$ and $f_2(1270)\pi$ [114], with a relative rate compatible with a hybrid state [88].

2. Heavy-light systems

Two very narrow states, $D_{s0}^*(2317)^\pm$ and $D_{s1}(2460)^\pm$, were observed at B factories [116,117]. They lie far below the predicted masses for the two expected broad P -wave $c\bar{s}$ mesons. These states have hence been interpreted as four-quark states [118–120] or DK (DK^*) molecules [121–123]. However, strong cusp effects, due to the nearby DK (DK^*) thresholds, could shift their masses downwards and quench the observed widths, an effect similar to that occurring for the $a_0(980)$ and $f_0(980)$ mesons, which lie just below $K\bar{K}$ threshold. A hadronic width of typically 100 keV would be the unequivocal signature for the molecular nature of $D_{s0}^*(2317)^\pm$ [123,124]. Its measured width is currently less than 3.8 MeV.

3. Heavy-heavy systems

A search for multiquark states containing a c (or a b) quark is promising since the charmonium spectrum can be predicted accurately, and because those mesons lying below the $D\bar{D}$ or $D\bar{D}^*$ thresholds should be narrow. Several states have been observed recently in the charmonium region. With the discovery of the $X(3872)$ in $B^\pm \rightarrow K^\pm X$ ($X \rightarrow J/\psi \pi^+\pi^-$) by Belle [126], soon confirmed by BaBar [127], many searches for states beyond the standard quark model were initiated both in the charm and in the bottom sectors. In the decay $\Lambda_b^0 \rightarrow J/\psi K^- p$ the LHCb collaboration has recently reported the observation of two new baryons decaying into $J/\psi p$, which are candidates for heavy pentaquark states [128]. For an updated collection of the currently available experimental information on multiquark states we refer to the mini-review on ‘Spectroscopy of mesons containing two heavy quarks’ in the *Meson Listings*.

When restricting ourselves to confirmed states we are faced with eight states that do not seem to fit into the standard quark model. This is clear for the four established charged states ($Z_c(3900)^\pm$ and $Z_c(4430)^\pm$ in the charmonium sector, and $Z_b(10610)^\pm$ and $Z_b(10650)^\pm$ in the bottomonium sector). The neutral ones ($X(3872)$, $Y(4260)$, $Y(4360)$, $Y(4660)$) also challenge the standard quark model since their masses and decay properties are in conflict with expectations.

The quantum numbers of the $X(3872)$ have been determined by LHCb to be $J^{PC} = 1^{++}$, first by assuming the angular momentum zero between the J/ψ and the dipion [129] and then by relaxing this constraint [130]. The $X(3872)$ can hardly be identified with the 2^3P_1 χ'_{c1} since the latter is predicted to lie about 100 MeV higher in mass [131]. Instead, the $X(3940)$ reported by Belle in $e^+e^- \rightarrow J/\psi X$, decaying into $D^*\bar{D}$ but not into $D\bar{D}$ [132], and also observed in $B \rightarrow K(X \rightarrow \omega J/\psi)$ [133] could be the χ'_{c1} . The 2^3P_2 tensor partner (χ'_{c2}) was reported by Belle at 3931 MeV in $\gamma\gamma$ interactions [134].

The $X(3872)$ lies close to the $D^0\bar{D}^{*0}$ threshold and therefore the most natural explanation for this state is a 1^{++} $D\bar{D}^*$ molecule [135] for which strong isospin breaking is predicted [135,136] due to the nearby D^+D^{*-} threshold. Indeed, the comparable rates for $\omega J/\psi$ and $\rho^0 J/\psi$ are consistent with an interpretation of $X(3872)$ as an isoscalar $D\bar{D}^*$ molecule when the different widths of the ρ and ω are taken into account [137]. A four-quark state $cq\bar{c}\bar{q}'$ is also possible [120] but unlikely, since the charged partner of the $X(3872)$ has not been observed (e.g. in $B^- \rightarrow \bar{K}^0 X^-$ nor in $B^0 \rightarrow K^+ X^-$, where $X^- \rightarrow J/\psi \pi^-\pi^0$ [138]). The claim that $X(3872)$ must be a compact (tetraquark) state, since it is also produced at very high p_T in $\bar{p}p$ collisions [139], was challenged in [140] which stresses the importance of rescattering, see also Ref. [141].

A broad structure, $Y(4260)$, decaying into $J/\psi \pi^+\pi^-$ was reported by BaBar in initial state radiation $e^+e^- \rightarrow \gamma(e^+e^- \rightarrow Y(4260))$ [142]. A charmonium state with the quantum numbers 1^{--} is not expected in this mass region. In addition,

See key on page 601

a charmonium at this mass should have a significant coupling to $\bar{D}D$, a decay channel that is not observed for the $Y(4260)$. This state could be a hybrid charmonium with a spin-1 $\bar{c}c$ core [143,144]. However, provided that the observation of $Y(4260)$ decay into $h_c(1P)\pi\pi$ by BESIII [145] is confirmed, the hybrid hypothesis would be under pressure, since the spin of the heavy quarks (coupled to zero in the $h_c(1P)$) should be conserved in leading order in the expansion in $(\Lambda_{\text{QCD}}/m_c)$. (The individual conservation of the heavy quark spin and the total angular momentum of the light quark cloud is a consequence of the heavy quark spin symmetry, see the review on ‘Heavy-Quark and Soft-Collinear Effective Theory’ in this issue of the *Review*.)

The same criticism applies to the hadrocharmonium interpretation of the $Y(4260)$ which describes this state as spin-1 quarkonium surrounded by a light quark cloud [146]. To circumvent the spin symmetry argument Ref. [147] argues that $Y(4260)$ and $Y(4360)$ could be mixtures of two hadrocharmonia with spin-triplet and spin-singlet heavy quark pairs. The same kind of mixing could also operate for a hybrid.

A dominant $D_1\bar{D}$ component in the $Y(4260)$ [148] would explain naturally why $Z_c(3900)^\pm$ (interpreted by the authors as a $\bar{D}D^*$ bound state) is seen in $Y(4260) \rightarrow \pi^\mp Z_c(3900)^\pm$. A prominent $D_1\bar{D}$ component in the $Y(4260)$ would in addition explain the copious production of $X(3872)$ in $Y(4260)$ radiative decays [149]. The $Y(4360)$ as $D_1\bar{D}^*$ bound state could be the spin partner of the $Y(4260)$ [150,151], but a detailed microscopic calculation is still lacking.

The tetraquark picture explains the observed Y states and, when including a tailor-made spin-spin interaction, is also capable to describe both $Z_c(3900)^{\pm,0}$ and $Z_c(4020)^\pm$ [152], and even the recently confirmed $Z(4430)^\pm$ by Belle [153]. However, the model predicts many additional charged and neutral states which have not yet been discovered.

The charged states $Z_c(3900)^\pm$, first observed by BESIII [154] and the to be confirmed $Z_c(4020)^\pm$ [155] decay predominantly into $\bar{D}D^*$ and \bar{D}^*D^* , respectively, while $Z_b(10610)^{\pm,0}$ and $Z_b(10650)^\pm$ [156,157] decay predominantly into $\bar{B}B^*$ and \bar{B}^*B^* , respectively, although all of them were discovered in the decay mode heavy quarkonium and pion. This suggests that the states are close relatives and their interactions are connected via heavy quark flavor symmetry. A molecular interpretation for the bottomonium states was proposed shortly after the discovery of the Z_b^\pm states [158] and also shortly after that of the $Z_c(3900)^\pm$ [148]. However, their properties also appear to be consistent with tetraquark structures [159].

The heaviest confirmed charged state in the charmonium sector is the $Z(4430)^\pm$ observed by Belle [153]. It is interpreted as hadrocharmonium [146], \bar{D}_1D^* molecule [160] as well as tetraquark state [152]. Alternatively, in [161] the $Z(4430)^\pm$ can be explained as a cross-channel effect.

It should be stressed that the various scenarios, while describing the data, also make decisive predictions, e.g. for other decay channels. The forthcoming data on heavy meson spectroscopy from various facilities should soon provide a much

deeper understanding on how QCD forms matter out of quarks and gluons.

$$|m_p - m_{\bar{p}}|/m_p$$

A test of *CPT* invariance. Note that the comparison of the \bar{p} and p charge-to-mass ratio, given in the next data block, is much better determined.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<7 × 10⁻¹⁰	90	¹ HORI	11	SPEC $\bar{p}e^-$ He atom
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<2 × 10 ⁻⁹	90	¹ HORI	06	SPEC $\bar{p}e^-$ He atom
<1.0 × 10 ⁻⁸	90	¹ HORI	03	SPEC $\bar{p}e^-$ ⁴ He, $\bar{p}e^-$ ³ He
<6 × 10 ⁻⁸	90	¹ HORI	01	SPEC $\bar{p}e^-$ He atom
<5 × 10 ⁻⁷		² TORII	99	SPEC $\bar{p}e^-$ He atom

¹ HORI 01, HORI 03, HORI 06, and HORI 11 use the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 99 (see below) to get their results. Their results are not independent of the HORI 01, HORI 03, HORI 06, and HORI 11 values for $|q_p + q_{\bar{p}}|/e$, below.

² TORII 99 uses the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 95 (see below) to get this result. This is not independent of the TORII 99 value for $|q_p + q_{\bar{p}}|/e$, below.

\bar{p}/p CHARGE-TO-MASS RATIO, $|q_{\bar{p}}/m_{\bar{p}}|/(q_p/m_p)$

A test of *CPT* invariance. Listed here are measurements involving the *inertial* masses. For a discussion of what may be inferred about the ratio of \bar{p} and p *gravitational* masses, see ERICSON 90; they obtain an upper bound of 10^{-6} – 10^{-7} for violation of the equivalence principle for \bar{p} 's.

VALUE	DOCUMENT ID	TECN	COMMENT
0.99999999991 ± 0.00000000009	GABRIELSE 99	TRAP	Penning trap
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1.0000000015 ± 0.0000000011	¹ GABRIELSE 95	TRAP	Penning trap
1.0000000023 ± 0.0000000042	² GABRIELSE 90	TRAP	Penning trap

¹ Equation (2) of GABRIELSE 95 should read $M(\bar{p})/M(p) = 0.999\,999\,9985(11)$ (G. Gabrielse, private communication).

² GABRIELSE 90 also measures $m_{\bar{p}}/m_{e^-} = 1836.152660 \pm 0.000083$ and $m_p/m_{e^-} = 1836.152680 \pm 0.000088$. Both are completely consistent with the 1986 CODATA (COHEN 87) value for m_p/m_{e^-} of 1836.152701 ± 0.000037 .

$$(|q_{\bar{p}}/m_{\bar{p}} - q_p/m_p)/q_p/m_p$$

A test of *CPT* invariance. Taken from the \bar{p}/p charge-to-mass ratio, above.

VALUE	DOCUMENT ID
(−9 ± 9) × 10⁻¹¹	OUR EVALUATION

$$|q_p + q_{\bar{p}}|/e$$

A test of *CPT* invariance. Note that the comparison of the \bar{p} and p charge-to-mass ratios given above is much better determined. See also a similar test involving the electron.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<7 × 10⁻¹⁰	90	¹ HORI	11	SPEC $\bar{p}e^-$ He atom
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<2 × 10 ⁻⁹	90	¹ HORI	06	SPEC $\bar{p}e^-$ He atom
<1.0 × 10 ⁻⁸	90	¹ HORI	03	SPEC $\bar{p}e^-$ ⁴ He, $\bar{p}e^-$ ³ He
<6 × 10 ⁻⁸	90	¹ HORI	01	SPEC $\bar{p}e^-$ He atom
<5 × 10 ⁻⁷		² TORII	99	SPEC $\bar{p}e^-$ He atom
<2 × 10 ⁻⁵		³ HUGHES	92	RVUE

¹ HORI 01, HORI 03, HORI 06, and HORI 11 use the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 99 (see above) to get their results. Their results are not independent of the HORI 01, HORI 03, HORI 06, and HORI 11 values for $|m_p - m_{\bar{p}}|/m_p$, above.

² TORII 99 uses the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 95 (see above) to get this result. This is not independent of the TORII 99 value for $|m_p - m_{\bar{p}}|/m_p$, above.

³ HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.

$$|q_p + q_e|/e$$

See BRESSI 11 for a summary of experiments on the neutrality of matter. See also “*n* CHARGE” in the neutron Listings.

VALUE	DOCUMENT ID	COMMENT
<1 × 10⁻²¹	¹ BRESSI	11 Neutrality of SF ₆
• • • We do not use the following data for averages, fits, limits, etc. • • •		
<3.2 × 10 ⁻²⁰	² SENGUPTA	00 binary pulsar
<0.8 × 10 ⁻²¹	MARINELLI	84 Magnetic levitation
<1.0 × 10 ⁻²¹	¹ DYLLA	73 Neutrality of SF ₆

¹ BRESSI 11 uses the method of DYLLA 73 but finds serious errors in that experiment that greatly reduce its accuracy. The BRESSI 11 limit assumes that $n \rightarrow p e^- \nu_e$ conserves charge. Thus the limit applies equally to the charge of the neutron.

² SENGUPTA 00 uses the difference between the observed rate of of rotational energy loss by the binary pulsar PSR B1913+16 and the rate predicted by general relativity to set this limit. See the paper for assumptions.

p MAGNETIC MOMENT

See the “Note on Baryon Magnetic Moments” in the *A* Listings.

- ¹DMITRIEV 03 calculates this limit from the limit on the electric dipole moment of the ¹⁹⁹Hg atom.
- ²This WILKENING 84 value includes a finite-size effect and a magnetic effect.
- ³This WILKENING 84 value is more cautious than the other and excludes the finite-size effect, which relies on uncertain nuclear integrals.

p ELECTRIC POLARIZABILITY α_p

For a very complete review of the “polarizability of the nucleon and Compton scattering,” see SCHUMACHER 05. His recommended values for the proton are α_p = (12.0 ± 0.6) × 10^{−4} fm³ and β_p = (1.9 ± 0.6) × 10^{−4} fm³, almost exactly our averages.

10.62 ± 1.25 ± 1.07 − 1.19 − 1.03	ZIEGER	92	CNTR γp Compton scattering
10.9 ± 2.2 ± 1.3	⁶ FEDERSPIEL	91	CNTR γp Compton scattering

- ¹BEANE 03 uses effective field theory and low-energy γp and γd Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) α_N = (13.0 ± 1.9 ± 3.9) × 10^{−4} fm³ and β_N = (−1.8 ± 1.9 ± 2.1) × 10^{−4} fm³.
- ²BLANPIED 01 gives α_p + β_p and α_p − β_p. The separate α_p and β_p are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.
- ³This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that α + β = (13.8 ± 0.4) × 10^{−4} fm³. See the paper for a discussion.
- ⁴MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a “global average” in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.
- ⁵BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum α_p + β_p.
- ⁶FEDERSPIEL 91 obtains for the (static) electric polarizability α_p, defined in terms of the induced electric dipole moment by **D** = 4πε₀α_p**E**, the value (7.0 ± 2.2 ± 1.3) × 10^{−4} fm³.

p MAGNETIC POLARIZABILITY β_p

The electric and magnetic polarizabilities are subject to a dispersion sum-rule constraint ᾱ + β̄ = (14.2 ± 0.5) × 10^{−4} fm³. Errors here are anticorrelated with those on ᾱ_p due to this constraint.

p CHARGE RADIUS

This is the rms electric charge radius, √⟨r_E²⟩.

Most measurements of the radius of the proton involve electron-proton interactions, and most of the more recent values agree with one another. The most precise of these is r_p = 0.879(8) fm (BERNAUER 10). The CODATA 14 value (MOHR 16), obtained from the electronic results, is 0.8751(61). Compared to this CODATA value, however, a measurement using muonic hydrogen finds r_p = 0.84087(39) fm (ANTOGNINI 13), which is 16 times more precise but differs by 5.6 standard deviations (using the CODATA 14 error).

Since POHL 10 (the first μp result), there has been a lot of discussion about the disagreement, especially concerning the modeling of muonic hydrogen. Here is an incomplete list of papers: DERUJULA 10, CLOET 11, DISTLER 11, DERUJULA 11, ARRINGTON 11, BERNAUER 11, HILL 11, LORENZ 14, KARSHENBOIM 14A, and PESET 15.

Until the difference between the ep and μp values is understood, it does not make sense to average the values together. For the present, we give both values. It is up to workers in this field to solve this puzzle.

See our 2014 edition (Chinese Physics C **38** 070001 (2014)) for values published before 2003.

Baryon Particle Listings

p

- ¹ ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of a neutron from the s shell of ^{12}C .
- ² AHMED 04 looks for γ rays from the de-excitation of a residual $^{15}\text{O}^*$ or $^{15}\text{N}^*$ following the disappearance of a neutron or proton in ^{16}O .
- ³ BACK 03 looks for decays of unstable nuclides left after N decays of parent ^{12}C , ^{13}C , ^{16}O nuclei. These are "invisible channel" limits.
- ⁴ ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO data in AHMAD 02.
- ⁵ AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.
- ⁶ BERNABEI 00b looks for the decay of a $^{128}_{53}\text{I}$ nucleus following the disappearance of a proton in the otherwise-stable $^{129}_{54}\text{Xe}$ nucleus.
- ⁷ EVANS 77 looks for the daughter nuclide ^{129}Xe from possible ^{130}Te decays in ancient Te ore samples.
- ⁸ This mean-life limit has been obtained from a half-life limit by dividing the latter by $\ln(2) = 0.693$.
- ⁹ FLEROV 58 looks for the spontaneous fission of a ^{232}Th nucleus after the disappearance of one of its nucleons.

\bar{p} MEAN LIFE

Of the two astrophysical limits here, that of GEER 00D involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also " \bar{p} Partial Mean Lives" after " p Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is 7×10^5 years, for $\bar{p} \rightarrow e^- \gamma$. We advance only the exclusive-mode limits to our Summary Tables.

LIMIT (years)	CL%	EVTs	DOCUMENT ID	TECN	COMMENT
• • •	We do not use the following data for averages, fits, limits, etc.	• • •			
>8 $\times 10^5$	90		¹ GEER 00D		\bar{p}/p ratio, cosmic rays

>1 $\times 10^7$			GOLDEN 79	SPEC	\bar{p}/p ratio, cosmic rays
>3.7 $\times 10^{-3}$			BREGMAN 78	CNTR	Storage ring
¹ GEER 00D uses agreement between a model of galactic \bar{p} production and propagation and the observed \bar{p}/p cosmic-ray spectrum to set this limit.					

p DECAY MODES

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1173) for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_j , where τ is the total mean life and B_j is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes.

Mode	Partial mean life (10 ³⁰ years)	Confidence level

ρ PARTIAL MEAN LIVES

The “partial mean life” limits tabulated here are the limits on τ/B_i , where τ is the total mean life for the proton and B_i is the branching fraction for the mode in question.

Decaying particle: p = proton, n = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

Antilepton + meson

¹ In estimating the background, this HIRATA 89c limit (as opposed to the later limits of WALL 00B and MCGREW 99) does not take into account present understanding that the flux of ν_μ originating in the upper atmosphere is depleted. Doing so would reduce the background and thus also would reduce the limit here.

² We have calculated 90% CL limit from 1 confined event.

³ We have converted 2 possible events to 90% CL limit.

⁴ We have converted half-life to 90% CL mean life.

¹ This ALLISON 98 limit is with no background subtraction; with subtraction the limit becomes $> 46 \times 10^{30}$ years.

² BARTELT 87 limit applies to $n \rightarrow \nu K_S^0$.

³ Limit based on zero events.

⁴ We have calculated 90% CL limit from 1 confined event.

⁵ We have converted 2 possible events to 90% CL limit.

$\tau(n \rightarrow \nu K_S^0)$

¹ ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of two neutrons from the s shell of ¹² C.						
² TRETYAK 04 uses data from an old Homestake-mine radiochemical experiment on limits for invisible decays of ³⁹ K to ³⁷ Ar.						
³ BACK 03 looks for decays of unstable nuclides left after NN decays of parent ¹² C, ¹³ C, ¹⁶ O nuclei. These are “invisible channel” limits.						
⁴ BERNABEI 00b looks for the decay of a ¹²⁷ Xe nucleus following the disappearance of an nn pair in the otherwise-stable ¹²⁹ Xe nucleus. The limit here applies as well to $nn \rightarrow \nu_\mu \bar{\nu}_\mu$, $nn \rightarrow \nu_\tau \bar{\nu}_\tau$, or any “disappearance” mode.						

$\tau(n n \rightarrow \nu_\mu \bar{\nu}_\mu)$							778
See the proceeding data block. "Invisible modes" would include any multi-neutrino mode.

n $I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: * * * *

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Anyone interested in the neutron should look at these two new review articles: D. Dubbers and M.G. Schmidt, "The neutron and its role in cosmology and particle physics," Reviews of Modern Physics **83** 1111 (2011); and F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," Reviews of Modern Physics **83** 1173 (2011).

n MASS (atomic mass units u)

The mass is known much more precisely in u (atomic mass units) than in MeV. See the next data block.

VALUE (u)	DOCUMENT ID	TECN	COMMENT
1.00866491588 ± 0.00000000049	MOHR	16	RVUE 2014 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1.00866491600 ± 0.00000000043	MOHR	12	RVUE 2010 CODATA value
1.00866491597 ± 0.00000000043	MOHR	08	RVUE 2006 CODATA value
1.00866491560 ± 0.00000000055	MOHR	05	RVUE 2002 CODATA value
1.00866491578 ± 0.00000000055	MOHR	99	RVUE 1998 CODATA value
1.0086655904 ± 0.0000000014	COHEN	87	RVUE 1986 CODATA value

n MASS (MeV)

The mass is known much more precisely in u (atomic mass units) than in MeV. The conversion from u to MeV, 1 u = 931.494 0054(57) MeV/c² (MOHR 16, the 2014 CODATA value), involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
939.5654133 ± 0.0000058	MOHR	16	RVUE 2014 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •

¹ The 2014 CODATA mass difference in *u* is $m_n - m_p = 1.001\,388\,449\,00(51) \times 10^{-3} u$.

² The 2010 CODATA mass difference in *u* is $m_n - m_p = 1.388\,449\,19(45) \times 10^{-3} u$.

³ Calculated by us from the MOHR 08 ratio $m_n/m_p = 1.00137841918(46)$. In *u*, $m_n - m_p = 1.38844920(46) \times 10^{-3} u$.

⁴ Calculated by us from the MOHR 05 ratio $m_n/m_p = 1.00137841870 \pm 0.00000000058$. In *u*, $m_n - m_p = (1.3884487 \pm 0.00000006) \times 10^{-3} u$.

⁵ Calculated by us from the MOHR 99 ratio $m_n/m_p = 1.00137841887 \pm 0.00000000058$. In *u*, $m_n - m_p = (1.3884489 \pm 0.00000006) \times 10^{-3} u$.

⁶ Calculated by us from the COHEN 87 ratio $m_n/m_p = 1.001378404 \pm 0.000000009$. In *u*, $m_n - m_p = 0.001388434 \pm 0.000000009 u$.

n MEAN LIFE

Limits on lifetimes for *bound* neutrons are given in the section “p PARTIAL MEAN LIVES.”

We average the best seven measurements. The result, 880.2 ± 1.0 s (including a scale factor of 1.9), is 5.5 seconds lower than the value we gave in 2010—a drop of 6.9 old and 5.5 new standard deviations.

For a full review of all matters concerning the neutron lifetime, see F.E. Wietfeldt and G.L. Greene, “The neutron lifetime,” *Reviews of Modern Physics* **83** 1173 (2011). In particular, there is a full discussion of the experimental methods and results; and an average lifetime is obtained making several different selections of the results then available.

¹ ARZUMANOV 15 is a reanalysis of their 2008–2010 dataset, with improved systematic corrections of ARZUMANOV 00 and ARZUMANOV 12.

² YUE 13 differs from NICO 05 in that a different and better method was used to measure the neutron density in the fiducial volume. This shifted the lifetime by +1.4 seconds and reduced the previously largest source of systematic uncertainty by a factor of five.

³ STEYERL 12 is a detailed reanalysis of neutron storage loss corrections to the raw data of MAMPE 89, and it replaces that value.

⁴ IGNATOVICH 95 calls into question some of the corrections and averaging procedures used by MAMPE 93. The response, BONDARENKO 96, denies the validity of the criticisms.

⁵ ARZUMANOV 12 reanalyzes its systematic corrections in ARZUMANOV 00 and obtains this corrected value.

⁶ The NESVIZHEVSKII 92 measurement has been withdrawn by A. Serebrov.

⁷ The BYRNE 80 measurement has been withdrawn (J. Byrne, private communication, 1990).

< 16	90	ALTAREV 79	MRS	$d = (4.0 \pm 7.5) \times 10^{-25}$

¹ SEREBROV 14 includes the data of ALTAREV 96.

² LAMOREAUX 07 faults BAKER 06 for not including in the estimate of systematic error an effect due to the Earth's rotation. BAKER 07 replies (1) that the effect was included implicitly in the analysis and (2) that further analysis confirms that the BAKER 06 limit is correct as is. See also SILENKO 07.

³ This HARRIS 99 result includes the result of SMITH 90. However, the averaging of the results of these two experiments has been criticized by LAMOREAUX 00.

n MEAN-SQUARE CHARGE RADIUS

The mean-square charge radius of the neutron, $\langle r_n^2 \rangle$, is related to the neutron-electron scattering length b_{ne} by $\langle r_n^2 \rangle = 3(m_e a_0 / m_n) b_{ne}$, where m_e and m_n are the masses of the electron and neutron, and a_0 is the Bohr radius. Numerically, $\langle r_n^2 \rangle = 86.34 b_{ne}$, if we use a_0 for a nucleus with infinite mass.

LIMIT ON $n\bar{n}$ OSCILLATIONSMean Time for $n\bar{n}$ Transition in Vacuum

A test of $\Delta B=2$ baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for $n\bar{n}$ oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, ALBERICO 91, and GAL 00 for discussions. Direct searches for $n \rightarrow \bar{n}$ transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table. See MOHAPATRA 09 for a recent review.

¹ NORMAN 96 gets this limit by attributing SAGE and GALLEX counting rates to the charge-nonconserving transition ${}^{71}\text{Ga} \rightarrow {}^{71}\text{Ge} + \text{neutrals}$ rather than to solar-neutrino reactions.

BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\bar{B}_f [f_1(q^2)\gamma_\lambda + i f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5q_\lambda] B_i. \quad (1)$$

Here B_i and \bar{B}_f are spinors describing the initial and final baryons, and $q = p_i - p_f$, while the terms in f_1 , f_2 , g_1 , and g_3 account for vector, induced tensor (“weak magnetism”), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V , and g_1 reduces to the axial-vector coupling constant g_A . The latter coefficients are related by Cabibbo’s theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an e^\pm is emitted, and gives a very small correction, which can be estimated by PCAC [4], for μ^\pm modes. Recoil effects

include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f}, \quad (2)$$

where m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher q^2 , it is necessary to modify the form factors at $q^2 = 0$ by a “dipole” q^2 dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio g_A/g_V may be written as

$$g_A/g_V = |g_A/g_V| e^{i\phi_{AV}}. \quad (3)$$

The presence of a “triple correlation” term in the transition probability, proportional to $\text{Im}(g_A/g_V)$ and of the form

$$\sigma_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (4)$$

for initial baryon polarization or

$$\sigma_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (5)$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ${}^{19}\text{Ne}$ nuclear beta decay), and the results are consistent with T invariance.

Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F m_\pi^2 \cdot \bar{B}_f (A - B\gamma_5) B_i, \quad (6)$$

where A and B are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma \hat{\omega}_f \cdot \hat{\omega}_i + (1 - \gamma)(\hat{\omega}_f \cdot \hat{\mathbf{n}})(\hat{\omega}_i \cdot \hat{\mathbf{n}}) + \alpha(\hat{\omega}_f \cdot \hat{\mathbf{n}} + \hat{\omega}_i \cdot \hat{\mathbf{n}}) + \beta \hat{\mathbf{n}} \cdot (\hat{\omega}_f \times \hat{\omega}_i), \quad (7)$$

where $\hat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\hat{\omega}_i$ and $\hat{\omega}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters α , β , and γ are defined as

$$\begin{aligned} \alpha &= 2 \text{Re}(s^*p)/(|s|^2 + |p|^2), \\ \beta &= 2 \text{Im}(s^*p)/(|s|^2 + |p|^2), \\ \gamma &= (|s|^2 - |p|^2)/(|s|^2 + |p|^2), \end{aligned} \quad (8)$$

Baryon Particle Listings

n

where $s = A$ and $p = |\mathbf{p}_f| B/(E_f + m_f)$; here E_f and \mathbf{p}_f are the energy and momentum of the final baryon. The parameters α , β , and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1. \quad (9)$$

If the hyperon polarization is \mathbf{P}_Y , the polarization \mathbf{P}_B of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \hat{\mathbf{n}})\hat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \hat{\mathbf{n}}) + \gamma\hat{\mathbf{n}} \times (\mathbf{P}_Y \times \hat{\mathbf{n}})}{1 + \alpha\mathbf{P}_Y \cdot \hat{\mathbf{n}}}. \quad (10)$$

Here \mathbf{P}_B is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\hat{\mathbf{n}}$ from the hyperon rest frame, in which $\hat{\mathbf{n}}$ and \mathbf{P}_Y are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\phi. \quad (11)$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α , ϕ , and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that $\beta = 0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s|e^{i\delta_s} \text{ and } p = |p|e^{i\delta_p}, \quad (12)$$

where δ_s and δ_p are the pion-baryon s - and p -wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s||p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p). \quad (13)$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \rightarrow p\pi^-$ decay, the value of Δ may be compared with the s - and p -wave phase shifts in low-energy π^-p scattering, and the results are consistent with T invariance.

See also the note on "Radiative Hyperon Decays" in the Ξ^0 Listings in this *Review*.

$\lambda \equiv g_A / g_V$

See key on page 601

Baryon Particle Listings

n

e^- ASYMMETRY PARAMETER A

This is the neutron-spin electron-momentum correlation coefficient. Unless otherwise noted, the values are corrected for radiative effects and weak magnetism. In the Standard Model, A is related to $\lambda \equiv g_A/g_V$ by $A = -2\lambda(\lambda+1)/(1+3\lambda^2)$; this assumes that g_A and g_V are real.

¹ EROZOLIMSKII 78 says asymmetric proton losses and nonuniform beam polarization may give a systematic error up to 30×10^{-4} , thus increasing the EROZOLIMSKII 74 error to 50×10^{-4} . STEINBERG 74 and STEINBERG 76 estimate these systematic errors to be insignificant in their experiment.

TRIPLE CORRELATION COEFFICIENT R

Another test of time-reversal invariance. R measures the polarization of the electron in the direction perpendicular to the plane defined by the neutron spin and the electron momentum. $R = 0$ for T invariance.

N AND Δ RESONANCES

Revised May 2015 by V. Burkert (Jefferson Lab), E. Klempt (University of Bonn), M.R. Pennington (Jefferson Lab), L. Tiator (University of Mainz), and R.L. Workman (George Washington University).

I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The Breit-Wigner masses and widths, the pole positions, and the elasticities of the *N* and Δ resonances in the Baryon Summary Table come largely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data. The most comprehensive analyses were carried out by the Karlsruhe-Helsinki (KH80) [1], Carnegie Mellon-Berkeley (CMB80) [2], and George Washington U (GWU) [3] groups. Partial-wave analyses have also been performed on much smaller πN reaction data sets to get ηN , $K\Lambda$, and $K\Sigma$ branching fractions (see the Listings for references). Other branching fractions come from analyses of $\pi N \rightarrow \pi\pi N$ data.

In recent years, a large amount of data on photoproduction of many final states has been accumulated, and these data are beginning to tell us much about the properties of baryon resonances. A survey of data on photoproduction can be found in the proceedings of recent conferences [4] and workshops [5], and in recent reviews [6,7].

See key on page 601

Baryon Particle Listings

N 's and Δ 's

Table 1. The status of the N resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

		Status as seen in									
Particle	J^P	overall	$N\gamma$	$N\pi$	$N\eta$	$N\sigma$	$N\omega$	ΛK	ΣK	$N\rho$	$\Delta\pi$
N	$1/2^+$	****									
$N(1440)$	$1/2^+$	****	****	****		***				*	***
$N(1520)$	$3/2^-$	****	****	****	***					***	***
$N(1535)$	$1/2^-$	****	****	****	****					**	*

$N(2600)$	$11/2^-$	***		***							
$N(2700)$	$13/2^+$	**		**							
****	Existence is certain, and properties are at least fairly well explored.										
***	Existence is very likely but further confirmation of decay modes is required.										
**	Evidence of existence is only fair.										
*	Evidence of existence is poor.										

II. Naming scheme for baryon resonances

In the past, when nearly all resonance information came from elastic πN scattering, it was common to label resonances with the incoming partial wave $L_{2I,2J}$, as in $\Delta(1232)P_{33}$ and $N(1680)F_{15}$. However, most recent information has come from γN experiments. Therefore, we have replaced $L_{2I,2J}$ with the spin-parity J^P of the state, as in $\Delta(1232)3/2^+$ and $N(1680)5/2^+$; this name gives intrinsic properties of the resonance that are independent of the specific particles and reactions used to study them. This applies equally to all baryons, including Ξ resonances and charm baryons that are not produced in formation experiments. We do not, however, attach the mass or spin-parity to the names of the ground-state (“stable”) baryons $N, \Lambda, \Sigma, \Xi, \Omega, \Lambda_c, \dots$.

III. Using the N and Δ listings

Tables 1 and 2 list all the N and Δ entries in the Baryon Listings and give our evaluation of the overall status and the status channel by channel. Only the established resonances (overall status 3 or 4 stars) are promoted to the Baryon Summary Table. We long ago omitted from the Listings information from old

analyses, prior to KH80 and CMB80, which can be found in earlier editions. A rather complete survey of older results was given in our 1982 edition [8].

Table 2. The status of the Δ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

		Status as seen in									
Particle	J^P	overall	$N\gamma$	$N\pi$	$N\eta$	$N\sigma$	$N\omega$	ΛK	ΣK	$N\rho$	$\Delta\pi$
$\Delta(1232)$	$3/2^+$	****	****	****	F						
$\Delta(1600)$	$3/2^+$	***	***	***	o					*	***
$\Delta(1620)$	$1/2^-$	****	***	****	r					***	***
$\Delta(1700)$	$3/2^-$	****	****	****	b					**	***
$\Delta(1750)$	$1/2^+$	*		*	i						
$\Delta(1900)$	$1/2^-$	**	**	**			d		**	**	**
$\Delta(1905)$	$5/2^+$	****	****	****			d		***	**	**
$\Delta(1910)$	$1/2^+$	****	**	****			e		*	*	**
$\Delta(1920)$	$3/2^+$	***	**	***			n	***		**	**
$\Delta(1930)$	$5/2^-$	***		***							
$\Delta(1940)$	$3/2^-$	**	**	*	F						
$\Delta(1950)$	$7/2^+$	****	****	****	o				***	*	***
$\Delta(2000)$	$5/2^+$	**			r					**	
$\Delta(2150)$	$1/2^-$	*		*	b						
$\Delta(2200)$	$7/2^-$	*		*	i						
$\Delta(2300)$	$9/2^+$	**		**	d						
$\Delta(2350)$	$5/2^-$	*		*	d						
$\Delta(2390)$	$7/2^+$	*		*	e						
$\Delta(2400)$	$9/2^-$	**		**	n						
$\Delta(2420)$	$11/2^+$	****	*	****							
$\Delta(2750)$	$13/2^-$	**		**							
$\Delta(2950)$	$15/2^+$	**		**							
****	Existence is certain, and properties are at least fairly well explored.										
***	Existence is very likely but further confirmation of decay modes is required.										
**	Evidence of existence is only fair.										
*	Evidence of existence is poor.										

As a rule, we award an overall status **** or *** only to those resonances which are derived from analyses of data sets that include precision differential cross sections and polarization observables, and are confirmed by independent analyses. All other signals are given ** or * status. We do not consider new results that are not accompanied by proper error evaluation. The following criteria are guidelines for future error analysis.

1. Uncertainties in resonance parameters: The publication must have a detailed discussion on how the uncertainties of parameters were estimated and why the author(s) believe that they approximately represent real uncertainties. This requires that the error estimates go beyond the simple fit error as e.g. given by MINUIT, and the robustness of the results must be demonstrated.

2. Fit quality: Concrete measures for the fit quality must be provided. The reduced global χ^2 value of the fit, while useful, is insufficient. Other possibilities include quoting variations of local χ^2 value in kinematic regions where evidence for new states or significantly improved information on resonance parameters is claimed.

3. Weight factors in observables: Analyses often use weight factors for certain data sets to either increase or reduce their

Baryon Particle Listings

N 's and Δ 's

impact on the results. This has been particularly important when polarization observables are involved, which usually are very sensitive to amplitude interferences but often have much poorer statistics than differential cross section data. To evaluate sensitivities, the resulting resonance parameters should be checked against variations of the specific weight factors.

Claims of evidence for new baryon states must be based on a sufficiently complete set of partial waves in the fit. The robustness of signals must be demonstrated, e.g. by examining the effect of higher waves in the fit.

IV. Properties of resonances

Resonances are defined by poles of the S -matrix, whether in scattering, production or decay matrix elements. These are poles in the complex plane in s , as discussed in the new review on *Resonances*. As traditional we quote here the pole positions in the complex energy $w = \sqrt{s}$ plane. Crucially, the position of the pole of the S -matrix is independent of the process, and the production and decay properties factorize. This is the rationale for listing the pole position first for each resonance.

These key properties of the S -matrix pole are in contrast to other quantities related to resonance phenomena, such as Breit-Wigner parameters or any K -matrix pole. Thus, Breit-Wigner parameters depend on the formalism used such as angular-momentum barrier factors, or cut-off parameters, and the assumed or modeled background. However, the accurate determination of pole parameters from the analysis of data on the real energy axis is not necessarily simple, or even straightforward. It requires the implementation of the correct analytic structure of the relevant (often coupled) channels. The example in the meson sector of the σ -pole highlights the need to incorporate right and left hand cut analyticity (and their relation imposed by crossing symmetry) into a dispersive analysis to obtain a robust determination of the pole position, for a very short-lived state close to the lowest threshold. The development of general methods that are simpler to implement in the baryon sector is a research problem of current interest, often exploiting techniques introduced long ago when the experimental data were far poorer than those presently available for reactions like $\gamma N \rightarrow \pi N$ [9]. No consensus yet exists for the use of any particular method, beyond the need to incorporate the general properties mentioned here and discussed more fully in the review of *Resonances*.

The tables will change in the following way: Pole positions, elastic and normalized inelastic residues appear first, followed by the Breit-Wigner mass, width, decay modes and branching ratios. Finally, we give the photon decay amplitudes first as complex values at the pole position and then as real numbers at the Breit-Wigner mass.

V. Photoproduction

A new approach to the nucleon excitation spectrum is provided by dedicated facilities at the Universities of Bonn, Grenoble, and Mainz, and at the national laboratories Jefferson

Lab in the US and SPring-8 in Japan. High-precision cross sections and polarization observables for the photoproduction of pseudoscalar mesons provide a data set that is nearly a “complete experiment,” one that fully constrains the four complex amplitudes describing the spin-structure of the reaction [11]. A large number of photoproduction reactions has been studied.

In pseudo-scalar meson photoproduction, the four independent helicity amplitudes can be expressed in terms of the four CGLN [12] amplitudes allowed by Lorentz and gauge invariance. These amplitudes can be expanded in a series of electric and magnetic multipoles. Except for $J=1/2$, one electric and one magnetic multipole contributes to each J^P combination.

For a given state, these two amplitudes determine the resonance photo-decay helicity amplitudes $A_{1/2}$ and $A_{3/2}$. As described below, this resonance extraction has been carried out either assuming a Breit-Wigner resonance or at the pole.

If a Breit-Wigner parametrization is used, the $N\gamma$ partial width, Γ_γ , is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_\gamma = \frac{k_{\text{BW}}^2}{\pi} \frac{2m_N}{(2J+1)m_{\text{BW}}} \left(|A_{1/2}|^2 + |A_{3/2}|^2 \right). \quad (1)$$

Here m_N and m_{BW} are the nucleon and resonance masses, J is the resonance spin, and k_{BW} is the photon c.m. decay momentum. Most earlier analyses have quoted these real quantities $A_{1/2}$ and $A_{3/2}$.

More recent studies have quoted related complex quantities, evaluated at the T-matrix pole. These complex helicity amplitudes, $\tilde{A}_{1/2}$ and $\tilde{A}_{3/2}$, can be cast onto the form

$$\tilde{A}_h = \sqrt{\frac{\pi(2J+1)w_{\text{pole}}}{m_N k_{\text{pole}}^2}} \frac{\text{Res}(T_h(\gamma N \rightarrow N b))}{\sqrt{\text{Res}(T(N b \rightarrow N b))}} \quad (2)$$

where the residues (Res) are evaluated at the pole position, w_{pole} , and $k_{\text{pole}}^2 = (w_{\text{pole}}^2 - m_N^2)^2 / 4w_{\text{pole}}^2$ [13]. For Breit-Wigner amplitudes, $w_{\text{pole}} = m_{\text{BW}}$ and $\tilde{A}_h = A_h$. Similar relations for the photo- and electrocouplings at the pole position can be found in [14,15].

The determination of eight real numbers from four complex amplitudes (with one overall phase undetermined) requires at least seven independent measurements. At least one further measurement is required to resolve discrete ambiguities that result from the fact that data are proportional to squared amplitudes. Photon beams and nucleon targets can be polarized (with linear or circular polarization P_\perp , P_\odot and \vec{T} , respectively); the recoil polarization of the outgoing baryon \vec{R} can be measured. The experiments can be divided into three classes: (1) the beam and target are polarized (BT); (2) the beam is polarized and the recoil baryon polarization is measured (BR); (3) the target is polarized and the recoil polarization is measured (TR). Different sign conventions are used in the literature, as summarized in [16].

One of the best studied reactions is $\gamma p \rightarrow \Lambda K^+$. Published data include differential cross sections, the beam asymmetry Σ , the target asymmetry T , the recoil polarization P , and the BR double-polarization variables C'_x, C'_z, O'_x , and O'_z . For the photoproduction of pions and etas, off proton and neutron targets, differential cross sections, single- and double-polarization asymmetries have been measured, mainly for pions.

VI. Electroproduction

Electro-production of mesons provides information on the internal structure of resonances. The helicity amplitudes are functions of the (squared) momentum transfer $Q^2 = -(e - e')^2$, where e and e' are the 4-momenta of the incident and scattered electron, and a third amplitude, $S_{1/2}$, measures the resonance response to the longitudinal component of the virtual photon. Most data stem from the reactions $e^- p \rightarrow e^- n \pi^+$ and $e^- p \rightarrow e^- p \pi^0$ but also the reactions $e^- p \rightarrow e^- p \eta$, $e^- p \rightarrow e^- p \pi^+ \pi^-$, and $e^- p \rightarrow e^- \Lambda(\Sigma^0) K^+$ have been studied. The data and their interpretation are reviewed in Refs. 18,19.

The transition to the $\Delta(1232)3/2^+$ is often quantified in terms of the magnetic dipole transition moment M_{1+} (or the magnetic transition form factor $G_{M,Ash}^*(Q^2)$) [20], and the electric and scalar quadrupole transition moments E_{1+} and S_{1+} . Figure 1 shows the strength of the $p \rightarrow \Delta^+$ transition plotted versus the photon virtuality Q^2 . At $Q^2 = 0$, M_{1+} dominates the resonance transition strength. The two amplitudes E_{1+} and S_{1+} imply a quadrupole deformation of the transition to the lowest excited state. The magnitude of $R_{EM} = E_{1+}/M_{1+}$ remains nearly constant, while the magnitude of $R_{SM} = S_{1+}/M_{1+}$ increases rapidly up to 25% at the highest Q^2 value. Dynamical models assign most of the quadrupole strength in the $p \Delta^+$ transition to the effect of a meson cloud around the bare Δ states.

Figure 1: Left: The magnetic transition form factor for the $\gamma^* p \rightarrow \Delta^+(1232)$ transition versus the photon virtuality Q^2 . Right: The electric and scalar quadrupole ratios R_{EM} and R_{SM} . The different symbols are results from different experiments at JLab (squares, diamonds, circle) and MAMI (triangle, cross). The boxes near the horizontal axis indicate model uncertainties of the squares. Curves to guide the eyes.

Figure 2 shows the transverse and scalar helicity amplitudes for the $N(1440)1/2^+$, $N(1520)3/2^-$, and $N(1535)1/2^-$ resonances from JLab [18]. Similar results have been achieved at Mainz [19]. For the states $N(1440)1/2^+$ and $N(1520)3/2^-$, helicity amplitudes and $\pi\Delta$ and ρp decays were determined at JLab in an analysis of $\pi^+ \pi^- p$ electroproduction [21]. The data show distinctly different Q^2 dependencies that indicate different internal structures.

Figure 2: Transverse and scalar (longitudinal) helicity amplitudes for $\gamma p \rightarrow N(1440)1/2^+$ (top), $\gamma p \rightarrow N(1520)3/2^-$ (center), and $\gamma p \rightarrow N(1535)1/2^-$ (bottom) as extracted from the JLab/CLAS data in $n\pi^+$ production (full circles), in $p\pi^+\pi^-$ (open triangles), combined single and double pion production (open squares). The solid triangle is the PDG 2014 value at $Q^2 = 0$. The open boxes are the model uncertainties of the full circles.

The $N(1520)3/2^-$ helicity amplitudes reveal the dominance of its three-quark nature: the $A_{3/2}$ amplitude is large at the photon point and decreases rapidly $\sim Q^{-5}$ with increasing Q^2 ; $A_{1/2}$ is small at the photon point, increases rapidly with Q^2 and then falls off with $\sim Q^{-3}$. Quantitative agreement with the data is, however, achieved only when meson cloud effects are included.

At high Q^2 , both amplitudes for $N(1440)1/2^+$ are qualitatively described by light front quark models [22]: at short distances the resonance behaves as expected from a radial excitation of the nucleon. On the other hand, $A_{1/2}$ changes sign at about 0.6 GeV^2 . This remarkable behavior has not been observed before for any nucleon form factor or transition amplitude. Obviously, an important change in the structure occurs when the resonance is probed as a function of Q^2 .

Baryon Particle Listings

N 's and Δ 's

The Q^2 dependence of $A_{1/2}$ of the $N(1535)1/2^-$ resonance exhibits the expected $\sim Q^{-3}$ dependence, except for small Q^2 values where meson cloud effects set in.

Figure 3: Transverse and scalar helicity amplitudes for $\gamma p \rightarrow N(1675)5/2^-$ (top), and $\gamma p \rightarrow N(1680)5/2^+$ (bottom) as extracted from the JLab/CLAS data in $n\pi^+$ production (full circles), combined single and double pion production (open square). The solid triangle is the 2014 PDG value at $Q^2 = 0$. The open boxes are the model uncertainties of the full circles. The curves are to guide the eye.

Figure 3 shows the transverse and scalar amplitudes for two states in the 3rd nucleon resonance region around 1700 MeV, the $N(1675)5/2^-$ and $N(1680)5/2^+$. These states have nearly degenerate masses and are parity partners. In the quark model picture, the transverse amplitudes for $N(1675)5/2^-$ on the proton are suppressed due to the Moorhouse selection rule, allowing for a quantitative evaluation of the meson-baryon contributions. The data show significant meson-baryon strength in the $A_{1/2}$ amplitude even at quite high Q^2 , while $A_{3/2}$ drops much faster with Q^2 . $N(1680)5/2^+$ shows qualitatively the features predicted in constituent quark models, a dominant $A_{3/2}$ at the real photon point that drops rapidly with increasing Q^2 , while $A_{1/2}$ becomes the dominant contribution at high Q^2 , indicating a switch of the helicity structure in the resonance transition at short distances.

VII. Partial wave analyses

Several PWA groups are now actively involved in the analysis of the new data. The GWU group maintains a nearly complete database covering reactions from πN and KN elastic scattering to $\gamma N \rightarrow N\pi$, $N\eta$, and $N\eta'$. It is presently the only group determining πN elastic amplitudes from scattering data in sliced energy bins. Given the high-precision of photoproduction data already or soon to be collected, the spectrum of N and Δ resonances will in the near future be better known.

Fits to the data are performed by various groups with the aim to understand the reaction dynamics and to identify N and Δ resonances. For practical reasons, approximations have to be made. We mention several analyses here: (1) The Mainz

unitary isobar model [23] focusses on the correct treatment of the low-energy domain. Resonances are added to the unitary amplitude as a sum of Breit-Wigner amplitudes. This model also obtains resonance transition form factors and helicity amplitudes from electroproduction [19]. (2) For $N\pi$ electroproduction, the Yerevan/JLab group uses both the unitary isobar model and the dispersion relation approach developed in [22]. A phenomenological model was developed to extract resonance couplings and partial decay widths from exclusive $\pi^+\pi^-p$ electroproduction [21]. (3) Multichannel analyses using K-matrix parameterizations derive background terms from a chiral Lagrangian - providing a microscopical description of the background - (Giessen [24,25]) or from phenomenology (KSU [26,27], Bonn-Gatchina [28]). (4.) Several groups (EBAC-Jlab [29,30], ANL-Osaka [31], Dubna-Mainz-Taipeh [32], Bonn-Jülich [33,34,35], Valencia [36]) use dynamical reaction models, driven by chiral Lagrangians, which take dispersive parts of intermediate states into account. Several other groups have made important contributions. The Giessen group pioneered multichannel analyses of large data sets on pion- and photo-induced reactions [24,25]. The Bonn-Gatchina group included recent high-statistics data and reported systematic searches for new baryon resonances in all relevant partial waves. A summary of their results can be found in Ref. 28.

$N(1520)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction (Γ_i/Γ)
Γ_1 $N\pi$	55–65 %
Γ_2 $N\eta$	< 1 %
Γ_3 $N\pi\pi$	25–35 %
Γ_4 $\Delta(1232)\pi$	22–34 %
Γ_5 $\Delta(1232)\pi$, S -wave	15–23 %
Γ_6 $\Delta(1232)\pi$, D -wave	7–11 %
Γ_7 $N\sigma$	< 2 %
Γ_8 $p\gamma$	0.31–0.52 %
Γ_9 $p\gamma$, helicity=1/2	0.01–0.02 %
Γ_{10} $p\gamma$, helicity=3/2	0.30–0.50 %
Γ_{11} $n\gamma$	0.30–0.53 %
Γ_{12} $n\gamma$, helicity=1/2	0.04–0.10 %
Γ_{13} $n\gamma$, helicity=3/2	0.25–0.45 %

$N(1520)$ FOOTNOTES

- ¹ Fit to the amplitudes of HOEHLER 79.
² MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze η photoproduction data. The ratio of the $A_{3/2}$ and $A_{1/2}$ amplitudes is determined, with less model dependence than the amplitudes themselves, to be $A_{3/2}/A_{1/2} = -2.5 \pm 0.5 \pm 0.4$.

$N(1535)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction (Γ_i/Γ)
Γ_1 $N\pi$	35–55 %
Γ_2 $N\eta$	32–52 %
Γ_3 $N\pi\pi$	3–14 %
Γ_4 $\Delta(1232)\pi$	
Γ_5 $\Delta(1232)\pi, D\text{-wave}$	1–4 %
Γ_6 $N\sigma$	2–10 %
Γ_7 $N(1440)\pi$	5–12 %
Γ_8 $p\gamma$, helicity=1/2	0.15–0.30 %
Γ_9 $n\gamma$, helicity=1/2	0.01–0.25 %

N(1650) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction (Γ_i/Γ)
Γ_1 $N\pi$	50–70 %
Γ_2 $N\eta$	14–22 %
Γ_3 ΛK	5–15 %
Γ_4 $N\pi\pi$	8–36 %
Γ_5 $\Delta(1232)\pi$	
Γ_6 $\Delta(1232)\pi, D\text{-wave}$	6–18 %
Γ_7 $N\sigma$	2–18 %
Γ_8 $N(1440)\pi$	6–26 %
Γ_9 $p\gamma, \text{ helicity}=1/2$	0.04–0.20 %
Γ_{10} $n\gamma, \text{ helicity}=1/2$	0.003–0.17 %

$N(1860) 5/2^+$

$I(J^P) = \frac{1}{2}(\frac{5}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a $J^P = 5/2^+$ state with a mass above 1800 MeV was filed under a two-star $N(2000)$. There is now some evidence from ANISOVICH 12A for two $5/2^+$ states in this region, so we have split the older data (according to mass) between two two-star $5/2^+$ states, an $N(1860)$ and an $N(2000)$.

N(2000) 5/2⁺

I(*J*^{*P*}) = $\frac{1}{2}(\frac{5}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a *J*^{*P*} = 5/2⁺ state with a mass above 1800 MeV was filed under a two-star *N*(2000). There is now some evidence from ANISOVICH 12A for two 5/2⁺ states in this region, so we have split the older data (according to mass) between two two-star 5/2⁺ states, an *N*(1860) and an *N*(2000).

¹ Fit to the amplitudes of HOEHLER 79.
² See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
³ The second (lower) value of HANSTEIN 96 here goes with the second (higher) value of the real part in the preceding data block.

0.058	HANSTEIN	96	DPWA $\gamma N \rightarrow \pi N$

Baryon Particle Listings

$\Delta(1232)$, $\Delta(1600)$

$\Delta(1232) \rightarrow N\gamma$, phase of E_2/M_1 ratio at pole

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
−122 ±5	ARNDT 97	DPWA	$\gamma N \rightarrow \pi N$
−127.2	HANSTEIN 96	DPWA	$\gamma N \rightarrow \pi N$

⁷ This ARNDT 97 value is very sensitive to the database being fitted. The result is from a fit to the full pion photoproduction database, apart from the BLANPIED 97 cross-section measurements.

$\Delta(1232)$ MAGNETIC MOMENTS

$\Delta(1232)^{++}$ MAGNETIC MOMENT

The values are extracted from UCLA and SIN data on $\pi^+ p$ bremsstrahlung using a variety of different theoretical approximations and methods. Our estimate is *only* a rough guess of the range we expect the moment to lie within.

Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE
We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a $\Delta(2850)$ and a $\Delta(3230)$. The evidence for them was deduced from total cross-section and 180° elastic cross-section measurements. The $\Delta(2850)$ has been resolved into the $\Delta(2750) I_{3,13}$ and $\Delta(2950) K_{3,15}$. The $\Delta(3230)$ is perhaps related to the $K_{3,13}$ of HENDRY 78 and to the $L_{3,17}$ of KOCH 80.

$\Delta(\sim 3000)$ BREIT-WIGNER MASS			
VALUE (MeV)	DOCUMENT ID	TECN	COMMENT

BARYON MAGNETIC MOMENTS

Written 1994 by C.G. Wohl (LBNL).

The figure below shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest

quark model, using the measured p , n , and Λ moments as input. In this model, the moments are [1]

$$\begin{aligned} \mu_p &= (4\mu_u - \mu_d)/3 & \mu_n &= (4\mu_d - \mu_u)/3 \\ \mu_{\Sigma^+} &= (4\mu_u - \mu_s)/3 & \mu_{\Sigma^-} &= (4\mu_d - \mu_s)/3 \\ \mu_{\Xi^0} &= (4\mu_s - \mu_u)/3 & \mu_{\Xi^-} &= (4\mu_s - \mu_d)/3 \\ \mu_\Lambda &= \mu_s & \mu_{\Sigma^0} &= (2\mu_u + 2\mu_d - \mu_s)/3 \\ & & \mu_{\Omega^-} &= 3\mu_s \end{aligned}$$

and the $\Sigma^0 \rightarrow \Lambda$ transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3}.$$

The quark moments that result from this model are $\mu_u = +1.852 \mu_N$, $\mu_d = -0.972 \mu_N$, and $\mu_s = -0.613 \mu_N$. The corresponding effective quark masses, taking the quarks to be Dirac point particles, where $\mu = q\hbar/2m$, are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 10.5$ for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

¹ CHAUVAT 85 actually gives $\alpha_+(\bar{\Lambda})/\alpha_-(\Lambda) = -1.04 \pm 0.29$. Assumes polarization is same in $\bar{p}\rho \rightarrow \bar{\Lambda}X$ and $p\rho \rightarrow \Lambda X$. Tests of this assumption, based on C -invariance and fragmentation, are satisfied by the data.

g_A / g_V FOR $\Lambda \rightarrow pe^-\bar{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the “Note on Baryon Decay Parameters” in the neutron Listings. The measurements all assume that the form factor $g_2 = 0$. See also the footnote on DWORKIN 90.

¹ The tabulated result assumes the weak-magnetism coupling $w \equiv g_W(0)/g_V(0)$ to be 0.97, as given by the CVC hypothesis and as assumed by the other listed measurements. However, DWORKIN 90 *measures* w to be 0.15 ± 0.30 , and then $g_A/g_V = -0.731 \pm 0.016$.

² This experiment measures only the absolute value of g_A/g_V .

Λ AND Σ RESONANCES

Introduction: Since our last edition, there have been a few measurements of properties of the lowest Λ and Σ resonances—mostly of masses and widths. But the field remains at a standstill. What follows is a much abbreviated version of the note on Λ and Σ Resonances from our 1990 edition [1]. In particular, see that edition for some representative Argand plots from partial-wave analyses.

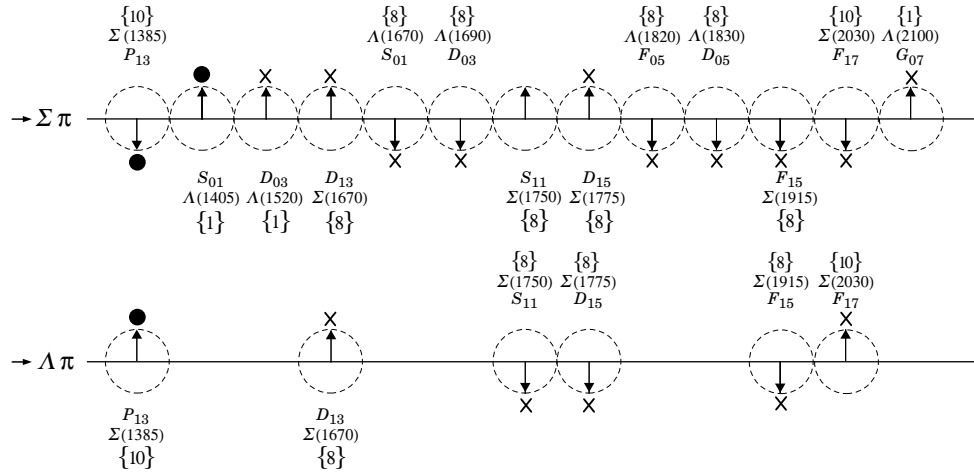

Figure 1. The signs of the imaginary parts of resonating amplitudes in the $\bar{K}N \rightarrow \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a \bullet , are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an \times .

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each Λ and Σ resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes A_0 and A_1 , the amplitude for $K^-p \rightarrow \bar{K}^0 n$ scattering is $\pm(A_1 - A_0)/2$, where

the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the “first” particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775)D_{15}$ amplitude at resonance points along the positive imaginary axis (points “up”), then any Σ at resonance will point “up” and any Λ at resonance will point “down” (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\bar{K}N \rightarrow \Lambda\pi$ and $\bar{K}N \rightarrow \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is “up”? Our convention is that of Levi-Setti [2] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or – sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign

means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [3].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a

Baryon Particle Listings

Λ 's and Σ 's, $\Lambda(1405)$

range reflecting the spread of the values rather than a particular value with error.

For three states, the $\Lambda(1520)$, the $\Lambda(1820)$, and the $\Sigma(1775)$, there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

Table 1. The status of the Λ and Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

**** Existence is certain, and properties are at least fairly well explored.
 *** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.
 ** Evidence of existence is only fair.
 * Evidence of existence is poor.

Production experiments: Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and

more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The $\Sigma(1385)$ and $\Lambda(1405)$ of course lie below the $\bar{K}N$ threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case of $\Lambda(1520)$ and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the note on the $\Sigma(1670)$.

$\Lambda(1405) \ 1/2^-$

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ****

The nature of the $\Lambda(1405)$ has been a puzzle for decades: three-quark state or hybrid; two poles or one. We cannot here survey the rather extensive literature. See, for example, CIEPLY 10, KISSLINGER 11, SEKIYARA 11, and SHEVCHENKO 12A for discussions and earlier references.

It seems to be the universal opinion of the chiral-unitary community that there are two poles in the 1400-MeV region. ZYCHOR 08 presents experimental evidence against the two-pole model, but this is disputed by GENG 07A. See also REVAI 09, which finds little basis for choosing between one- and two-pole models; and IKEDA 12, which favors the two-pole model.

A single, ordinary three-quark $\Lambda(1405)$ fits nicely into a $J^P = 1/2^-$ $SU(4)$ $\bar{4}$ multiplet, whose other members are the $\Lambda_c(2595)^+$, $\Xi_c(2790)^+$, and $\Xi_c(2790)^0$; see Fig. 1 of our note on “Charmed Baryons.”

POLE STRUCTURE OF THE $\Lambda(1405)$ REGION

Written November 2015 by Ulf-G. Meißner (Bonn Univ. / FZ Jülich) and Tetsuo Hyodo (YITP, Kyoto Univ.).

The $\Lambda(1405)$ resonance emerges in the meson-baryon scattering amplitude with the strangeness $S = -1$ and isospin $I = 0$. It is the archetype of what is called a dynamically generated resonance, as pioneered by Dalitz and Tuan [1]. The most powerful and systematic approach for the low-energy regime of the strong interactions is chiral perturbation theory (ChPT), see e.g. Ref. 2. A perturbative calculation is, however, not applicable to this sector because of the existence of the $\Lambda(1405)$ just below the $\bar{K}N$ threshold. In this case, ChPT has to be combined with a non-perturbative resummation technique, just as in the case of the nuclear forces. By solving the Lippmann-Schwinger equation with the interaction kernel determined by ChPT and using a particular regularization, in Ref. 3 a successful description of the low-energy K^-p scattering data as well as the mass distribution of the $\Lambda(1405)$ was achieved (for further developments, see Ref. 4 and references therein).

The study of the pole structure was initiated by Ref. 5, which finds two poles of the scattering amplitude in the complex energy plane between the $\bar{K}N$ and $\pi\Sigma$ thresholds. The spectrum in experiments exhibits one effective resonance shape,

while the existence of two poles results in the reaction-dependent lineshape [6]. The origin of this two-pole structure is attributed to the two attractive channels of the leading order interaction in the SU(3) basis (singlet and octet) [6] and in the isospin basis ($\bar{K}N$ and $\pi\Sigma$) [7]. It is remarkable that the sign and the strength of the leading order interaction is determined by a low-energy theorem of chiral symmetry, i.e. the so-called Weinberg-Tomozawa term. The two-pole nature of the $\Lambda(1405)$ is qualitatively different from the case of the N(1440) resonance. Two poles of the N(1440) appear on different Riemann sheets of the complex energy plane separated by the $\pi\Delta$ branch point. These poles reflect a single state, with a nearby pole and a more distant shadow pole. In contrast, the two poles in the $\Lambda(1405)$ region on the same Riemann sheet (where $\pi\Sigma$ channels are unphysical and all other channels physical, correspondingly to the one, connected to the real axis between the $\pi\Sigma$ and $\bar{K}N$ thresholds) are generated from two attractive forces mentioned above [6,7].

Recently, various new experimental results on the $\Lambda(1405)$ have become available [4]. Among these, the most striking measurement is the precise determination of the energy shift and width of kaonic hydrogen by the SIDDHARTA collaboration [8], [9], which provides a quantitative and stringent constraint on the K^-p amplitude at threshold through the improved Deser formula [10]. Systematic studies with error analyses based on the next-to-leading order ChPT interaction including the SIDDHARTA constraint have been performed by various groups [11–15]. All these studies confirm that the new kaonic hydrogen data are compatible with the scattering data above threshold.

Table 1: Comparison of the pole positions of $\Lambda(1405)$ in the complex energy plane from next-to-leading order chiral unitary coupled-channel approaches including the SIDDHARTA constraint.

approach	pole 1 [MeV]	pole 2 [MeV]
Refs. 11,12, NLO	$1424^{+7}_{-23} - i 26^{+3}_{-14}$	$1381^{+18}_{-6} - i 81^{+19}_{-8}$
Ref. 14, Fit II	$1421^{+3}_{-2} - i 19^{+8}_{-5}$	$1388^{+9}_{-9} - i 114^{+24}_{-25}$
Ref. 15, solution #2	$1434^{+2}_{-2} - i 10^{+2}_{-1}$	$1330^{+4}_{-5} - i 56^{+17}_{-11}$
Ref. 15, solution #4	$1429^{+8}_{-7} - i 12^{+2}_{-3}$	$1325^{+15}_{-15} - i 90^{+12}_{-18}$

The results of the pole positions of $\Lambda(1405)$ in the various approaches are summarized in Table 1. We may regard the difference among the calculations as a systematic error, which stems from the various approximations of the Bethe-Salpeter equation, the fitting procedure, and also the inclusion of SU(3) breaking effects such as the choice of the various meson decay constants, and so on. The main component for the $\Lambda(1405)$ is the pole 1, whose position converges within a relatively small region near the $\bar{K}N$ threshold. On the other hand, the position of the pole 2 shows a sizeable scatter. Detailed studies of the $\pi\Sigma$ spectrum in various reaction processes, together with

the precise experimental lineshape (see e.g. the recent precise photoproduction data from the LEPS collaboration [16] and from the CLAS collaboration [17,18], electroproduction data from the CLAS collaboration [19], and proton-proton collision data from COSY [20] and the HADES collaboration [21]), will shed light on the position of the second pole. The $\pi\Sigma$ spectra from the CLAS data and the HADES data are analyzed in Ref. 22 and Ref. 23, respectively. Although the result of the pole positions in Ref. 22 is similar to those in Table 1, the pole found in Ref. 23 is not compatible with other results. Therefore, the analysis with only the $\pi\Sigma$ spectrum is not completely conclusive. It is thus desirable to perform a comprehensive analysis of $\pi\Sigma$ spectra together with the systematic error analysis of the scattering data as done in Ref. 15. It was shown there that several solutions, which agree with the scattering data are ruled out, if confronted with the recent CLAS data. The remaining solutions are collected as solution #2 and solution #4 of Ref. 15 in Table 1.

$\Lambda(1405)$ FOOTNOTES

- ¹ DALITZ 91 fits the HEMINGWAY 85 data.
- ² THOMAS 73 data is fit by CHAO 73 (see next section).
- ³ The KIMURA 00 values are from fits A and B from a coupled-channel potential model using low-energy $\bar{K} N$ and $\Sigma \pi$ data, kaonic-hydrogen x-ray measurements, and our $\Lambda(1405)$ mass and width. The results bear mainly on the *nature* of the $\Lambda(1405)$: three-quark state or $\bar{K} N$ bound state.
- ⁴ The MARTIN 81 fit includes the $K^\pm p$ forward scattering amplitudes and the dispersion relations they must satisfy.
- ⁵ See also the accompanying paper of THOMAS 73.
- ⁶ Data of SAKITT 65 are used in the fit by KITTEL 66.
- ⁷ An asymmetric shape, with $\Gamma/2 = 41$ MeV below resonance, 14 MeV above.

$\Lambda(1520) \ 3/2^-$

$I(J^P) = 0(\frac{3}{2}^-)$ Status: * * * *

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters **111B** 1 (1982).

Production and formation experiments agree quite well, so they are listed together here.

See key on page 601

CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 28 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 18.9$ for 23 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Gamma(\Sigma(1385)\pi(\rightarrow\Lambda\pi\pi))/\Gamma(\Lambda\pi\pi)$	Γ_5/Γ_3
The $\Lambda\pi\pi$ mode is largely due to $\Sigma(1385)\pi$. Only the values of $(\Sigma(1385)\pi)/(\Lambda 2\pi)$ given by MAST 73b and CORDEN 75 are based on real 3-body partial-wave analyses. The discrepancy between the two results is essentially due to the different hypotheses made concerning the shape of the $(\pi\pi)_{\text{S-wave}}$ state.

 $\Lambda(1670)$ FOOTNOTES

- ¹ GARCIA-RECIO 03 gives pole, not Breit-Wigner, parameters, but the narrow width of the $\Lambda(1670)$ means there will be little difference.
² MARTIN 77 obtains identical resonance parameters from a T-matrix pole and from a Breit-Wigner fit.

$\Lambda(1690)$ DECAY MODES		
	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	20–30 %
Γ_2	$\Sigma\pi$	20–40 %
Γ_3	$\Lambda\pi\pi$	~ 25 %
Γ_4	$\Sigma\pi\pi$	~ 20 %
Γ_5	$\Lambda\eta$	
Γ_6	$\Sigma(1385)\pi$, S -wave	
The above branching fractions are our estimates, not fits or averages.		

$\Lambda(1690)$ BRANCHING RATIOS			
The sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma \pi \pi$ bump looks more significant. (The error given for the $\Lambda \pi \pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma \pi \pi$ decay can be via $\Sigma(1385)$, for then seven times as much $\Lambda \pi \pi$ decay would be required. See “Sign conventions for resonance couplings” in the Note on Λ and Σ Resonances.

- $\Lambda(1690)$ FOOTNOTES**
- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another $D_{03} \ \Lambda$ at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.

² BARTLEY 68 uses only cross-section data. The enhancement is not seen by PREVOST 71.

$\Lambda(1820) \ 5/2^+$

$I(J^P) = 0(\frac{5}{2}^+)$ Status: ***

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

 $\Lambda(1820)$ FOOTNOTES

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
² There is a suggestion of a bump, enough to be consistent with what is expected from $\Sigma(1385) \rightarrow \Sigma\pi$ decay.
³ The published sign has been changed to be in accord with the baryon-first convention.

$$I(J^P) = 0(?)^? \quad \text{Status: } *$$

OMITTED FROM SUMMARY TABLE

ZHANG 13A claims a $J^P = 1/2^-$ state.

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are D_3 (BARBARO-GALTIERI 70 in $\Sigma\pi$), D_3+F_5 , P_3+D_5 , or P_1+D_3 (BRANDSTETER 72 in $\Lambda\omega$), and S_1 (CAMERON 78B in $N\bar{K}^*$). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

$\Lambda(2000)$ FOOTNOTES

- ¹ The parameters quoted here are ranges from the three best fits; the lower state probably has $J \leq 3/2$, and the higher one probably has $J \leq 5/2$.
- ² The published sign has been changed to be in accord with the baryon-first convention.

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\bar{K}$ or $\Sigma\pi$. With new K^-n angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters **170B** 1 (1986).

$\Lambda(2100)$ FOOTNOTES

- ¹ The NAKKASYAN 75 values are from the two best solutions found. Each has the $\Lambda(2100)$ and one additional resonance (P_3 or F_5).
- ² Note that the three for BACCARI 77 entries are for three different waves.
- ³ The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the G_3 wave is 0.03.

$\Lambda(2325) \ 3/2^-$

$I(J^P) = 0(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P = 3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $K^-p \rightarrow \Lambda\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^-p \rightarrow \bar{K}N$ data, and finds $J^P = 3/2^-$ or $3/2^+$. They again prefer $J^P = 3/2^-$, but only on the basis of model-dependent considerations.

$\Lambda(2350) \ 9/2^+$

$I(J^P) = 0(\frac{9}{2}^+)$ Status: ***

DAUM 68 favors $J^P = 7/2^-$ or $9/2^+$. BRICMAN 70 favors $9/2^+$. LASINSKI 71 suggests three states in this region using a Pomeron + resonances model. There are now also three formation experiments from the College de France-Saclay group, DEBELLEFON 77, BACCARI 77, and DEBELLEFON 78, which find $9/2^+$ in energy-dependent partial-wave analyses of $\bar{K}N \rightarrow \Sigma\pi$, $\Lambda\omega$, and $N\bar{K}$.

0.83 ± 0.032	1300	⁴ CHANG	66	HBC

³ This is a measurement of the $\bar{\Sigma}^-$ lifetime. Here we assume CPT invariance; see below for the fractional $\Sigma^+ - \bar{\Sigma}^-$ lifetime difference obtained by BARBOSA 00.
⁴ We have increased the CHANG 66 error of 0.018; see our 1970 edition, Reviews of Modern Physics **42** 87 (1970).

$(\tau_{\Sigma^+} - \tau_{\Sigma^-}) / \tau_{\Sigma^+}$

A test of CPT invariance.

VALUE	DOCUMENT ID	TECN	COMMENT
(-6 ± 12) × 10⁻⁴	BARBOSA	00	E761 hyperons, 375 GeV

Σ^+ MAGNETIC MOMENT

See the "Note on Baryon Magnetic Moments" in the Λ Listings. Measurements with an error $\geq 0.1 \mu_N$ have been omitted.

VALUE (μ_N)	EVTS	DOCUMENT ID	TECN	COMMENT
2.458 ± 0.010 OUR AVERAGE				Error includes scale factor of 2.1. See the ideogram below.
2.4613 ± 0.0034 ± 0.0040	250k	MORELOS	93	SPEC p Cu 800 GeV
2.428 ± 0.036 ± 0.007	12k	⁵ MORELOS	93	SPEC p Cu 800 GeV
2.479 ± 0.012 ± 0.022	137k	WILKINSON	87	SPEC p Be 400 GeV
2.4040 ± 0.0198	44k	⁶ ANKENBRA...	83	CNTR p Cu 400 GeV

⁵ We assume CPT invariance: this is (minus) the $\bar{\Sigma}^-$ magnetic moment as measured by MORELOS 93. See below for the moment difference testing CPT .
⁶ ANKENBRANDT 83 gives the value $2.38 \pm 0.02 \mu_N$. MORELOS 93 uses the same hyperon magnet and channel and claims to determine the field integral better, leading to the revised value given here.

$(\mu_{\Sigma^+} + \mu_{\Sigma^-}) / \mu_{\Sigma^+}$

A test of CPT invariance.

VALUE	DOCUMENT ID	TECN	COMMENT
0.014 ± 0.015	⁷ MORELOS	93	SPEC p Cu 800 GeV

⁷ This is our calculation from the MORELOS 93 measurements of the Σ^+ and $\bar{\Sigma}^-$ magnetic moments given above. The statistical error on $\mu_{\bar{\Sigma}^-}$ dominates the error here.

Σ^+ DECAY MODES

Mode	Fraction (Γ_i/Γ)	Confidence level

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.7$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

	¹³ ANG 69B	HBC	$K^- p$ at rest

¹³ ANG 69B found three $pe^+ e^-$ events in agreement with $\gamma \rightarrow e^+ e^-$ conversion from $\Sigma^+ \rightarrow p\gamma$. The limit given here is for neutral currents.

$\Gamma(p\mu^+\mu^-)/\Gamma_{\text{total}}$				Γ_9/Γ
A test for a $\Delta S = 1$ weak neutral current, but also allowed by higher-order electroweak interactions.				
VALUE (units 10^{-8})	EVTS	DOCUMENT ID	TECN	COMMENT
$8.6^{+6.6}_{-5.4} \pm 5.5$	3	¹⁴ PARK	05	HYCP p Cu, 800 GeV

¹⁴ The masses of the three dimuons of PARK 05 are within 1 MeV of one another, perhaps indicating the existence of a new state P^0 with mass 214.3 ± 0.5 MeV. In that case, the decay is $\Sigma^+ \rightarrow pP^0$, $P^0 \rightarrow \mu^+ \mu^-$, with a branching fraction of $(3.1^{+2.4}_{-1.9} \pm 1.5) \times 10^{-8}$.

Σ^0

$I(J^P) = 1(\frac{1}{2}^+)$ Status: * * * *

COURANT 63 and ALFF 65, using $\Sigma^0 \rightarrow \Lambda e^+ e^-$ decays (Dalitz decays), determined the Σ^0 parity to be positive, given that $J = 1/2$ and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the Σ^0 mean life and $\Sigma^0 \rightarrow \Lambda$ transition magnetic moment come (see below), strongly support $J = 1/2$.

Σ^0 MASS

The fit uses Σ^+ , Σ^0 , Σ^- , and Λ mass and mass-difference measurements.

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \rightarrow \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0 - Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma\Lambda}/\mu_N)^2 \tau = 1.92951 \times 10^{-19}$ s (see DEVLIN 86).

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 8.7$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

g_A/g_V FOR $\Sigma^- \rightarrow n e^- \bar{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the “Note on Baryon Decay Parameters” in the neutron Listings. What is actually listed is $|g_1/f_1 - 0.237g_2/f_1|$. This reduces to $g_A/g_V \equiv g_1(0)/f_1(0)$ on making the usual assumption that $g_2 = 0$. See also the note on HSUEH 88.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.340±0.017 OUR AVERAGE				
+0.327±0.007±0.019	50k	⁷ HSUEH	88	SPEC Σ^- 250 GeV

0.385±0.037	3507	⁹ TANENBAUM	74	ASPK
● ● ● We do not use the following data for averages, fits, limits, etc. ● ● ●				
0.29 ±0.07	25k	HSUEH	85	SPEC See HSUEH 88
0.17 ^{+0.07} _{-0.09}	519	DECAMP	77	ELEC Hyperon beam

⁷ The sign is, with our conventions, unambiguously positive. The value assumes, as usual, that $g_2 = 0$. If g_2 is included in the fit, than (with our sign convention) $g_2 = -0.56 \pm 0.37$, with a corresponding reduction of g_A/g_V to $+0.20 \pm 0.08$.

⁸ BOURQUIN 83c favors the positive sign by at least 2.6 standard deviations.

⁹ TANENBAUM 74 gives 0.435 ± 0.035 , assuming no q^2 dependence in g_A and g_V . The listed result allows q^2 dependence, and is taken from HSUEH 88.

$f_2(0)/f_1(0)$ FOR $\Sigma^- \rightarrow n e^- \bar{\nu}_e$

The signs have been changed to be in accord with our conventions, given in the “Note on Baryon Decay Parameters” in the neutron Listings.

$\Sigma(1385)$ $\Sigma(1385) \ 3/2^+$

$$I(J^P) = 1(\frac{3}{2}^+) \text{ Status: } ****$$

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** S1 (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a P -wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLMGREN 77 obtains a good fit to their $\Lambda\pi$ spectrum with a P -wave Breit-Wigner, but includes the partial width for the $\Sigma\pi$ decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S -wave results are given here.

$\Sigma(1385)$ FOOTNOTES

- ¹ From fit to inclusive $\Lambda\pi$ spectrum.
² Includes data of HOLMGREN 77.
³ The errors are statistical only. The resolution is not unfolded.
⁴ The error is enlarged to Γ/\sqrt{N} . See the note on the $K^*(892)$ mass in the 1984 edition.
⁵ From a fit to $\Lambda\pi^0$ with the width fixed at 34 MeV.
⁶ From fit to inclusive $\Lambda\pi^0$ spectrum with the width fixed at 40 MeV.
⁷ Redundant with data in the mass Listings.
⁸ Results from $\Lambda\pi^+\pi^-$ and $\Lambda\pi^+\pi^-\pi^0$ combined by us.
⁹ The error is enlarged to $4\Gamma/\sqrt{N}$. See the note on the $K^*(892)$ mass in the 1984 edition.
¹⁰ Consistent with +, 0, and – widths equal.
¹¹ KELLER 12 gives $\Gamma(\Sigma^+\gamma)/\Gamma(\Sigma^+\pi^0) = (11.95 \pm 2.21^{+0.53}_{-1.21})\%$, using 1/2 our total $\Sigma(1385) \rightarrow \Sigma\pi$ fraction for $\Sigma^+\pi^0$. We divide the KELLER 12 value by two.
¹² We calculate this from the MOLCHANOV 04 upper limit of 9.5 keV on the $\Sigma^-\gamma$ width.
¹³ We calculate this from the ARIK 77 upper limit of 24 keV on the $\Sigma^-\gamma$ width.
¹⁴ An extrapolation of the parametrized amplitude below threshold.

OMITTED FROM SUMMARY TABLE
These are peaks seen in $\Lambda\pi$ and $\Sigma\pi$ spectra in the reaction $\pi^+ p \rightarrow (\gamma\pi) K^+$ at 1.7 GeV/c. Also, the γ polarization oscillates in the same region.

MILLER 70 suggests a possible alternate explanation in terms of a reflection of $N(1675) \rightarrow \Lambda K$ decay. However, such an explanation for the $(\Sigma^+\pi^0) K^+$ channel in terms of $\Delta(1650) \rightarrow \Sigma K$ decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the γ polarization in the 1480 MeV region.

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in $K^- p \rightarrow \Lambda\pi^0$.

ENGELN 80 performs a multichannel analysis of $K^- p \rightarrow p\bar{K}^0\pi^-$ at 4.2 GeV/c. They observe a 3.5 standard-deviation signal at 1480 MeV in $p\bar{K}^0$ which cannot be explained as a reflection of any competing channel.

PRAKHOV 04 sees no evidence for this or other light Σ resonances, aside from the $\Sigma(1385)$, in $K^- p \rightarrow \Lambda\pi^0\pi^0$.

ZYCHOR 06 finds peaks in $pp \rightarrow pK^+(\pi^\pm X^\mp)$ at $p_{\text{beam}} = 3.65$ GeV/c.

OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged $\Lambda/\Sigma\pi$ mass spectra from $K^-p \rightarrow (\Lambda/\Sigma)\pi K\bar{K}$ at 4.2 GeV/c. In a CERN ISR experiment, LOCKMAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in $\Lambda\pi^\pm$ from the reaction $pp \rightarrow \Lambda\pi^+\pi^-X$. These enhancements are unlikely to be associated with the $\Sigma(1580)$ (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1 $\bar{K}N$ total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

OMITTED FROM SUMMARY TABLE		
Seen in the isospin-1 $\bar{K}N$ cross section at BNL (LI 73, CARROLL 76) and in a partial-wave analysis of $K^-p \rightarrow \Lambda\pi^0$ for c.m. energies 1560–1600 MeV by LITCHFIELD 74. LITCHFIELD 74 finds $J^P = 3/2^-$. Not seen by ENGLER 78 or by CAMERON 78C (with larger statistics in $K_L^0 p \rightarrow \Lambda\pi^+$ and $\Sigma^0\pi^+$).		
Neither OLMSTED 04 (in $K^-p \rightarrow \Lambda\pi^0$) nor PRAKHOV 04 (in $K^-p \rightarrow \Lambda\pi^0\pi^0$) see any evidence for this state.

$\Sigma(1580)$ FOOTNOTES	
¹ CARROLL 76 sees a total-cross-section bump with $(J+1/2)\Gamma_{\text{el}}/\Gamma_{\text{total}} = 0.06$.	
² The main effect observed by LITCHFIELD 74 is in the $\Lambda\pi$ final state; the $\bar{K}N$ and $\Sigma\pi$ couplings are estimated from a multichannel fit including total-cross-section data of LI 73.

THE $\Sigma(1670)$ REGION

Production experiments: The measured $\Sigma\pi/\Sigma\pi\pi$ branching ratio for the $\Sigma(1670)$ produced in the reaction $K^-p \rightarrow \pi^-\Sigma(1670)^+$ is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two Σ resonances with the same mass and quantum numbers: one with a large $\Sigma\pi\pi$ (mainly $\Lambda(1405)\pi$) branching fraction produced peripherally, and the other with a large $\Sigma\pi$ branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the $\Sigma\pi$ and the $\Lambda(1405)\pi$ states are D_{13} . There is also possibly a third Σ in this region, the $\Sigma(1690)$ in the Listings, the main evidence for which is a large $\Lambda\pi/\Sigma\pi$ branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

Formation experiments: Two states are also observed near this mass in formation experiments. One of these, the $\Sigma(1670)D_{13}$, has the same quantum numbers as those observed in production and has a large $\Sigma\pi/\Sigma\pi\pi$ branching ratio; it may well be the $\Sigma(1670)$ produced at larger angles (see TIMMERMANS 76). The other state, the $\Sigma(1660)P_{11}$, has different quantum numbers, its $\Sigma\pi/\Sigma\pi\pi$ branching ratio is unknown, and its relation to the produced $\Sigma(1670)$ states is obscure.

See key on page 601

Baryon Particle Listings

$\Sigma(1670)$

$\Sigma(1670) \ 3/2^-$

$$I(J^P) = 1(\frac{3}{2}^-) \text{ Status: } ****$$

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

Results from production experiments are listed separately in the next entry.

Baryon Particle Listings

$\Sigma(1670)$, $\Sigma(1670)$ Bumps

$\Sigma(1670)$ FOOTNOTES

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
² Results are with and without an S_{11} $\Sigma(1620)$ in the fit.
³ Ratio only for $\Sigma 2\pi$ system in $l = 1$, which cannot be $\Sigma(1385)$.
⁴ SIMS 68 uses only cross-section data. Result used as upper limit only.
⁵ Assuming the $\Lambda(1405)\pi$ cross-section bump is due only to $3/2^-$ resonance.
⁶ The CAMERON 77 upper limit on F -wave decay is 0.03.

$\Sigma(1670)$ Bumps

$$I(J^P) = 1(?)^?$$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the preceding entry.

Probably there are two states at the same mass with the same quantum numbers, one decaying to $\Sigma\pi$ and $\Lambda\pi$, the other to $\Lambda(1405)\pi$. See the note in front of the preceding entry.

$J^P = 3/2^+$		LEVEQUE 65	HBC		$\Lambda(1405) \pi$

 $\Sigma(1670)$ FOOTNOTES

- ¹ Total cross-section bump with $(J+1/2) \Gamma_{\text{el}} / \Gamma_{\text{total}} = 0.23$.
² Enhancements in $\Sigma \pi$ and $\Sigma \pi \pi$ cross sections.
³ Backward production in the $\Lambda \pi^- K^+$ final state.
⁴ Depending on production angle.
⁵ APSELL 74, ESTES 74, and TIMMERMAN576 find strong branching ratio dependence on production angle, as in earlier production experiments.

 $\Sigma(1690)$ FOOTNOTES
(PRODUCTION EXPERIMENTS)

- ¹ From $\pi^+ p \rightarrow (\Lambda \pi^+) K^+$. $J > 1/2$ is not required by the data.
² From $\pi^+ p \rightarrow (\Lambda \pi^+) (K \pi)^+$. $J > 1/2$ is indicated, but large background precludes a definite conclusion.
³ See the $\Sigma(1670)$ Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the $\Sigma(1690)$.
⁴ This analysis, which is difficult and requires several assumptions and shows no unambiguous $\Sigma(1690)$ signal, suggests $J^P = 5/2^+$. Such a state would lead all previously known Y^* trajectories.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to N \overline{K} and Λπ, as well as to Ση whose threshold is at 1746 MeV (JONES 74).

OMITTED FROM SUMMARY TABLE

Evidence for this state now rests solely on solution 1 of BAILLON 75, (see the footnotes) but the $\Lambda\pi$ partial-wave amplitudes of this solution are in disagreement with amplitudes from most other $\Lambda\pi$ analyses. ZHANG 13A finds no evidence for this state.

$\Sigma(1770)$ FOOTNOTES

- ¹ Required to fit the isospin-1 total cross section of CARROLL 76 in the $\bar{K}N$ channel. The addition of new K^-p polarization and K^-n differential cross-section data in GOPAL 80 find it to be more consistent with the $\Sigma(1660) P_{11}$.
² From solution 1 of BAILLON 75; not present in solution 2.
³ Not required in KANE 74, which supersedes KANE 72.

$\Sigma(1775)$ $5/2^-$

$$I(J^P) = 1(\frac{5}{2}^-) \text{ Status: } ****$$

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the $\Lambda(1820) F_{05}$ does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

$\Sigma(1775)$ DECAY MODES

Mode	Fraction (Γ_i/Γ)
Γ_1	$N\bar{K}$
Γ_2	$\Lambda\pi$
Γ_3	$\Sigma\pi$
Γ_4	$\Sigma(1385)\pi$
Γ_5	$\Sigma(1385)\pi$, D-wave
Γ_6	$\Lambda(1520)\pi$, P-wave
Γ_7	$\Sigma\pi\pi$
Γ_8	$\Delta(1232)\bar{K}$, D-wave
Γ_9	$N\bar{K}^*(892)$, S=1/2
Γ_{10}	$N\bar{K}^*(892)$, S=3/2, D-wave

The above branching fractions are our estimates, not fits or averages.

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 18 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 363.4$ for 14 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	-44			
x_3	-23	10

$\Sigma(1775)$ FOOTNOTES

- The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- The CAMERON 78 upper limit on G-wave decay is 0.03.
- This rate combines P-wave- and F-wave decays. The CAMERON 77 results for the separate P-wave- and F-wave decays are -0.303 ± 0.010 and -0.037 ± 0.014 . The published signs have been changed here to be in accord with the baryon-first convention.
- For about 3/4 of this, the $\Sigma\pi$ system has $l=0$ and is almost entirely $\Lambda(1520)$. For the rest, the $\Sigma\pi$ has $l=1$, which is about what is expected from the known $\Sigma(1775) \rightarrow \Sigma(1385)\pi$ rate, as seen in $\Lambda\pi\pi$.

¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.		
² From solution 1 of BAILLON 75; not present in solution 2.		
³ Only unconstrained states from table 1 of LEA 73 are listed.		
⁴ The published sign has been changed to be in accord with the baryon-first convention.

Baryon Particle Listings
 $\Sigma(1915), \Sigma(1940)$

$\Sigma(1915) \ 5/2^+$

$I(J^P) = 1(\frac{5}{2}^+)$ Status: ****

Discovered by COOL 66. For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions in this region used to be listed in a separate entry immediately following. They may be found in our 1986 edition Physics Letters **170B** 1 (1986).

$\Sigma(1915)$ FOOTNOTES

- 1 The two entries for CORDEN 77c are from two different acceptable solutions.
2 Preferred solution 3; see CORDEN 76 for other possibilities.
3 The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
4 The mass and width are fixed to the GOPAL 77 values due to the low elasticity.
5 The published sign has been changed to be in accord with the baryon-first convention.

$\Sigma(2070) 5/2^+$

$I(J^P) = 1(\frac{5}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

This state suggested by BERTHON 70B finds support in GOPAL 80 with new K^-p polarization and K^-n angular distributions. The very broad state seen in KANE 72 is not required in the later (KANE 74) analysis of $\bar{K}N \rightarrow \Sigma\pi$.

See key on page 601

$\Sigma(2250)$	$I(J^P) = 1(?^?)$ Status: ***
Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\overline{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\overline{K}N \rightarrow \Lambda\pi$, $\Sigma\pi$, and $N\overline{K}$, respectively, suggest two resonances around this mass.

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction $K^- p \rightarrow Y^{*+} \pi^-$ using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a $K^- p$ experiment in LASS at 11 GeV/c (ASTON 85B).

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 11 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 7.5$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

RADIATIVE HYPERON DECAYS

Revised July 2011 by J.D. Jackson (LBNL).

The weak radiative decays of spin-1/2 hyperons, $B_i \rightarrow B_f \gamma$, yield information about matrix elements (form factors) similar to that gained from weak hadronic decays. For a polarized spin-1/2 hyperon decaying radiatively via a $\Delta Q = 0$, $\Delta S = 1$

transition, the angular distribution of the direction $\hat{\mathbf{p}}$ of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{dN}{d\Omega} = \frac{N}{4\pi} (1 + \alpha_{\gamma} \mathbf{P}_i \cdot \hat{\mathbf{p}}) . \quad (1)$$

Here \mathbf{P}_i is the polarization of the decaying hyperon, and α_{γ} is the asymmetry parameter. In terms of the form factors $F_1(q^2)$, $F_2(q^2)$, and $G(q^2)$ of the effective hadronic weak electromagnetic vertex,

$$F_1(q^2)\gamma_{\lambda} + iF_2(q^2)\sigma_{\lambda\mu}q^{\mu} + G(q^2)\gamma_{\lambda}\gamma_5 ,$$

α_{γ} is

$$\alpha_{\gamma} = \frac{2 \operatorname{Re}[G(0)F_M^*(0)]}{|G(0)|^2 + |F_M(0)|^2} , \quad (2)$$

where $F_M = (m_i - m_f)[F_2 - F_1/(m_i + m_f)]$. If the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = -\alpha_{\gamma}$ [1].

The angular distribution for the weak hadronic decay, $B_i \rightarrow B_f \pi$, has the same form as Eq. (1), but of course with a different asymmetry parameter, α_{π} . Now, however, if the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = +\alpha_{\pi}$ [2,3]. The difference of sign is because the spins of the pion and photon are different.

$\Xi^0 \rightarrow \Lambda \gamma$ decay—The radiative decay $\Xi^0 \rightarrow \Lambda \gamma$ of an unpolarized Ξ^0 uses the hadronic decay $\Lambda \rightarrow p\pi^-$ as the analyzer. As noted above, the longitudinal polarization of the Λ will be $P_{\Lambda} = -\alpha_{\Xi\Lambda\gamma}$. Let α_{-} be the $\Lambda \rightarrow p\pi^-$ asymmetry parameter and $\theta_{\Lambda p}$ be the angle, as seen in the Λ rest frame, between the Λ line of flight and the proton momentum. Then the hadronic version of Eq. (1) applied to the $\Lambda \rightarrow p\pi^-$ decay gives

$$\frac{dN}{d\cos\theta_{\Lambda p}} = \frac{N}{2} (1 - \alpha_{\Xi\Lambda\gamma} \alpha_{-} \cos\theta_{\Lambda p}) \quad (3)$$

for the angular distribution of the proton in the Λ frame. Our current value, from the CERN NA48/1 experiment [4], is $\alpha_{\Xi\Lambda\gamma} = -0.704 \pm 0.019 \pm 0.064$.

$\Xi^0 \rightarrow \Sigma^0 \gamma$ decay—The asymmetry parameter here, $\alpha_{\Xi\Sigma\gamma}$, is measured by following the decay chain $\Xi^0 \rightarrow \Sigma^0 \gamma$, $\Sigma^0 \rightarrow \Lambda \gamma$, $\Lambda \rightarrow p\pi^-$. Again, for an unpolarized Ξ^0 , the longitudinal polarization of the Σ^0 will be $P_{\Sigma} = -\alpha_{\Xi\Sigma\gamma}$. In the $\Sigma^0 \rightarrow \Lambda \gamma$ decay, a parity-conserving magnetic-dipole transition, the polarization of the Σ^0 is transferred to the Λ , as may be seen as follows. Let $\theta_{\Sigma\Lambda}$ be the angle seen in the Σ^0 rest frame between the Σ^0 line of flight and the Λ momentum. For Σ^0 helicity +1/2, the probability amplitudes for positive and negative spin states of the Σ^0 along the Λ momentum are $\cos(\theta_{\Sigma\Lambda}/2)$ and $\sin(\theta_{\Sigma\Lambda}/2)$. Then the amplitude for a negative helicity photon and a negative helicity Λ is $\cos(\theta_{\Sigma\Lambda}/2)$, while the amplitude for positive helicities for the photon and Λ is $\sin(\theta_{\Sigma\Lambda}/2)$. For Σ^0 helicity -1/2, the amplitudes are interchanged. If the Σ^0 has longitudinal polarization P_{Σ} , the probabilities for Λ helicities $\pm 1/2$ are therefore

$$p(\pm 1/2) = \frac{1}{2}(1 \mp P_{\Sigma}) \cos^2(\theta_{\Sigma\Lambda}/2) + \frac{1}{2}(1 \pm P_{\Sigma}) \sin^2(\theta_{\Sigma\Lambda}/2) , \quad (4)$$

Baryon Particle Listings

 Ξ^0, Ξ^-

and the longitudinal polarization of the Λ is

$$P_{\Lambda} = -P_{\Sigma} \cos \theta_{\Sigma\Lambda} = +\alpha_{\Xi\Sigma\gamma} \cos \theta_{\Sigma\Lambda} . \quad (5)$$

Using Eq. (1) for the $\Lambda \rightarrow p\pi^-$ decay again, we get for the joint angular distribution of the $\Sigma^0 \rightarrow \Lambda\gamma$, $\Lambda \rightarrow p\pi^-$ chain,

$$\frac{d^2 N}{d \cos \theta_{\Sigma\Lambda} d \cos \theta_{\Lambda p}} = \frac{N}{4} (1 + \alpha_{\Xi\Sigma\gamma} \cos \theta_{\Sigma\Lambda} \alpha_- \cos \theta_{\Lambda p}) . \quad (6)$$

Our current average for $\alpha_{\Xi\Sigma\gamma}$ is -0.69 ± 0.06 [4,5].

References

1. R.E. Behrends, Phys. Rev. **111**, 1691 (1958); see Eq. (7) or (8).
2. In ancient times, the signs of the asymmetry term in the angular distributions of radiative and hadronic decays of polarized hyperons were sometimes opposite. For roughly 50 years, however, the overwhelming convention has been to make them the same. The aim, not always achieved, is to remove ambiguities.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 5 parameters. The overall fit has a χ² = 1.0 for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients <δx_iδx_j>/(δx_iδx_j), in percent, from the fit to the branching fractions, x_i ≡ Γ_i/Γ_{total}. The fit constrains the x_i whose labels appear in this array to sum to one.

8 This LUK 00 value is for $\alpha(\Xi^+)\alpha_+(\bar{\Lambda})$. We assume CP conservation here by including it in the average for $\alpha(\Xi^-)\alpha_-(\Lambda)$. But see the second data block below for the CP test.

α FOR Ξ⁻ → Λπ⁻
The above average, $\alpha(\Xi^-)\alpha_-(\Lambda) = -0.294 \pm 0.005$, where the error includes a scale factor of 1.7, divided by our current average $\alpha_-(\Lambda) = 0.642 \pm 0.013$, gives the following value for $\alpha(\Xi^-)$.

VALUE	DOCUMENT ID
-0.458 ± 0.012 OUR EVALUATION	Error includes scale factor of 1.8.

$\frac{[\alpha(\Xi^-)\alpha_-(\Lambda) - \alpha(\Xi^+)\alpha_+(\bar{\Lambda})]}{[\alpha(\Xi^-)\alpha_-(\Lambda) + \alpha(\Xi^+)\alpha_+(\bar{\Lambda})]}$
This is zero if CP is conserved. The α 's are the decay-asymmetry parameters for $\Xi^- \rightarrow \Lambda\pi^-$ and $\Lambda \rightarrow p\pi^-$ and for $\Xi^+ \rightarrow \bar{\Lambda}\pi^+$ and $\bar{\Lambda} \rightarrow \bar{p}\pi^+$.

0 ± 20.4	364	¹² LONDON	66	HBC Using $\alpha_\Lambda = 0.62$
54 ± 30	356	¹² CARMONY	64b	HBC

⁹ From this result and α_Ξ , HUANG 04 gets $\beta_\Xi = -0.037 \pm 0.011 \pm 0.010$ and $\gamma_\Xi = 0.888 \pm 0.0004 \pm 0.006$. And the strong p-s phase difference for $\Lambda\pi^-$ scattering is $(4.6 \pm 1.4 \pm 1.2)^\circ$.

¹⁰ From this result and α_Ξ , CHAKRAVORTY 03 obtains $\beta_\Xi = -0.025 \pm 0.042 \pm 0.006$ and $\gamma_\Xi = 0.889 \pm 0.001 \pm 0.007$. And the strong p-s phase difference for $\Lambda\pi^-$ scattering is $(3.17 \pm 5.28 \pm 0.73)^\circ$.

¹¹ BENSINGER 85 used $\alpha_\Lambda = 0.642 \pm 0.013$.

¹² The errors have been multiplied by 1.2 due to approximations used for the Ξ polarization; see DAUBER 69 for a discussion.

g_A / g_V FOR Ξ⁻ → Λe⁻ν_e

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
-0.25 ± 0.05	1992	¹³ BOURQUIN	83	SPEC SPS hyperon beam

¹³ BOURQUIN 83 assumes that $g_2 = 0$. Also, the sign has been changed to agree with our conventions, given in the “Note on Baryon Decay Parameters” in the neutron Listings.

Ξ RESONANCES

The accompanying table gives our evaluation of the present status of the Ξ resonances. Not much is known about Ξ resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few μb), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about Ξ resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in the 1980's did electronic experiments make any significant contributions. However, nothing of significance on Ξ resonances has been added since our 1988 edition.

For a detailed earlier review, see Meadows [1].

Table 1. The status of the Ξ resonances. Only those with an overall status of *** or **** are included in the Baryon Summary Table.

Particle	J^P	Overall status	Status as seen in —				
			$\Xi\pi$	ΛK	ΣK	$\Xi(1530)\pi$	Other channels
$\Xi(1318)$	$1/2^+$	****					Decays weakly
$\Xi(1530)$	$3/2^+$	****	****				
$\Xi(1620)$		*	*				
$\Xi(1690)$		***		***	**		
$\Xi(1820)$	$3/2^-$	***	**	***	**	**	
$\Xi(1950)$		***	**	**		*	
$\Xi(2030)$		***		**	***		
$\Xi(2120)$		*		*			
$\Xi(2250)$		**					3-body decays
$\Xi(2370)$		**					3-body decays
$\Xi(2500)$		*		*	*		3-body decays
****	Existence is certain, and properties are at least fairly well explored.						
***	Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.						
**	Evidence of existence is only fair.						
*	Evidence of existence is poor.						

Reference

1. B.T. Meadows, in *Proceedings of the IVth International Conference on Baryon Resonances* (Toronto, 1980), ed. N. Isgur, p. 283.

$\Xi(1530) 3/2^+$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^+) \text{ Status: } ****$$

This is the only Ξ resonance whose properties are all reasonably well known. Assuming that the Λ_c^+ has $J^P = 1/2^+$, AUBERT 08AK, in a study of $\Lambda_c^+ \rightarrow \Xi^- \pi^+ K^+$, finds conclusively that the spin of the $\Xi(1530)^0$ is $3/2$. In conjunction with SCHLEIN 63B and BUTTON-SHAFFER 66, this proves also that the parity is +.

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

$\Xi(1690)$

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

AUBERT 08AK, in a study of $\Lambda_c^+ \rightarrow \Xi^- \pi^+ K^+$, finds some evidence that the $\Xi(1690)$ has $J^P = 1/2^-$.

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma^- \overline{K}$ mass spectra in $K^-p \rightarrow (\Sigma^- \overline{K}) K \pi$ at 4.2 GeV/c. The data from the $\Sigma^- \overline{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\Lambda^- \overline{K}$ channels, and a coupled-channel analysis yields results consistent with a new Ξ .

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced ΛK^- system. A peak is also observed in the $\Lambda \overline{K}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\Sigma^- \overline{K}^0$, with the γ from the Σ^- decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of Ξ^- into ΛK^- . The significance claimed is 6.7 standard deviations.

ADAMOVICH 98 sees a peak of 1400 ± 300 events in the $\Xi^- \pi^+$ spectrum produced by 345 GeV/c Σ^- -nucleus interactions.

$\Xi(1820) 3/2^-$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^-) \text{ Status: } ***$$

The clearest evidence is an 8-standard-deviation peak in ΛK^- seen by GAY 76C. TEODORO 78 favors $J = 3/2$, but cannot make a parity discrimination. BIAGI 87C is consistent with $J = 3/2$ and favors negative parity for this J value.

$\Xi(1820)$ MASS

We only average the measurements that appear to us to be most significant and best determined.

$\Xi(1950)$ $I(J^P) = \frac{1}{2}(?)^?$ Status: * * *

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a Ξ near 1950 MeV seems strong enough to include a $\Xi(1950)$ in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one Ξ near this mass.

 $\Xi(2030)$

$$J(P) = \frac{1}{2} (\geq \frac{5}{2}?) \text{ status: } ***$$

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in $\Sigma \bar{K}$ and a weaker coupling to $\Lambda \bar{K}$. ALITTI 68 and HEMINGWAY 77 observe no signals in the $\Xi \pi \pi$ (or $\Xi(1530) \pi$) channel, in contrast to DIBIANCA 75. The decay $(\Lambda/\Sigma) \bar{K} \pi$ reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that $J \geq 5/2$.

$\Xi(2120)$ FOOTNOTES

- ¹ CHLIAPNIKOV 79 does not uniquely identify the K^+ in the $(\bar{\Lambda} K^+) X$ final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV.
² GAY 76c sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u . This suggests an anomalous production mechanism if the $\Xi(2120)$ is real.

The evidence for this state is mixed. BARTSCH 69 sees a bump of not much statistical significance in $\Lambda\bar{K}\pi$, $\Sigma\bar{K}\pi$, and $\Xi\pi\pi$ mass spectra. GOLDWASSER 70 sees a narrower bump in $\Xi\pi\pi$ at a higher mass. Not seen by HASSALL 81 with 45 events/ μb at 6.5 GeV/c. Seen by JENKINS 83. Perhaps seen by BIAGI 87.

Baryon Particle Listings

Ω^-

Ω BARYONS
($S = -3, I = 0$)

$\Omega^- = sss$

Ω^-

$I(J^P) = 0(\frac{3}{2}^+)$ Status: ***

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out $J = 1/2$ and find consistency with $J = 3/2$. AUBERT, BE 06 finds from the decay angular distributions of $\Xi_c^0 \rightarrow \Omega^- K^+$ and $\Omega_c^0 \rightarrow \Omega^- K^+$ that $J = 3/2$; this depends on the spins of the Ξ_c^0 and Ω_c^0 being $J = 1/2$, their supposed values.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Ω^- MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them together.

1670.6 ± 1.0	1	² FRY 55B	EMUL	
1615	1	⁴ EISENBERG 54	EMUL	

- ¹DIBIANCA 75 gives a mass for each event. We quote the average.
- ²The FRY 55 and FRY 55B events were identified as Ω^- by ALVAREZ 73. The masses assume decay to ΛK^- at rest. For FRY 55B, decay from an atomic orbit could Doppler shift the K^- energy and the resulting Ω^- mass by several MeV. This shift is negligible for FRY 55 because the Ω decay is approximately perpendicular to its orbital velocity, as is known because the Λ strikes the nucleus (L.Alvarez, private communication 1973). We have calculated the error assuming that the orbital n is 4 or larger.
- ³Excluded from the average; the Ω^- lifetimes measured by the experiments differ significantly from other measurements.
- ⁴The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the Ω interacted with an Ag nucleus to give $K^- \Xi \text{Ag}$.

- ⁵ This KAMAEV 10 value uses 76 $\Omega^- \rightarrow \Xi^- \pi^+ \pi^-$ and 24 $\overline{\Omega}^+ \rightarrow \Xi^+ \pi^- \pi^+$ decays. The Ω^- and $\overline{\Omega}^+$ branching fractions measurements are statistically equal. The errors given combine statistical and systematic contributions. The CP branching-fraction asymmetry, $(\Omega^- - \overline{\Omega}^+)/\text{sum}$, is $+0.12 \pm 0.20$.

OMITTED FROM SUMMARY TABLE

A peak in the $\Omega^-\pi^+\pi^-$ mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

CHARMED BARYONS ($C = +1$)

$$\begin{aligned}\Lambda_c^+ &= udc, & \Sigma_c^{++} &= uuc, & \Sigma_c^+ &= udc, & \Sigma_c^0 &= ddc, \\ \Xi_c^+ &= usc, & \Xi_c^0 &= dsc, & \Omega_c^0 &= ssc\end{aligned}$$

CHARMED BARYONS

Revised March 2012 by C.G. Wohl (LBNL).

(Note added November 2015.) Since the 2014 *Review*, there have been three papers that improved the values of the masses and/or widths of the $\Sigma(2455)$, $\Sigma(2520)$, Ξ_c^+ , Ξ_c^0 , $\Xi_c(2645)$, $\Xi_c(2970)$, $\Xi_c(3055)$, and $\Xi_c(3080)$. See the Listings for those particles.

There are 18 known charmed baryons, and four other candidates not well enough established to be promoted to the Summary Tables.* Fig. 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The Λ_c and Σ_c spectra ought to look much like the Λ and Σ spectra, since a Λ_c or a Σ_c differs from a Λ or a Σ only by the replacement of the s quark with a c quark. However, a Ξ or an Ω has more than one s quark, only *one* of which is changed to a c quark to make a Ξ_c or an Ω_c . Thus the Ξ_c and Ω_c spectra ought to be richer than the Ξ and Ω spectra.**

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells what charmed baryons to expect; this is essential, because few of the spin-parity values given in Fig. 1(a) have been measured.

Fig. 1. (a) The known charmed baryons, and (b) the lightest “4-star” strange baryons. Note that there are two $J^P = 1/2^+$ Ξ_c states, and that the lightest Ω_c does not have $J = 3/2$. The $J^P = 1/2^+$ states, all tabbed with a circle, belong to the SU(4) multiplet that includes the nucleon; states with a circle and the same fill belong to the same SU(3) multiplet within that SU(4) multiplet. Similar remarks apply to the other states: same shape of tab, same SU(4) multiplet; same fill of that shape, same SU(3) multiplet. The $J^P = 1/2^-$ and $3/2^-$ states tabbed with triangles complete two SU(4) 4 multiplets.

But far and away the most important advance for c -baryons this edition is the first ever (!) model-independent measurement of a Λ_c^+ branching fraction. The anchor for all the other Λ_c^+ fractions is the $pK^-\pi^+$ fraction. Our value for many editions, $(5.0 \pm 1.3)\%$, was cobbled together from two ancient model-dependent measurements. Now, thanks to the Belle experiment, it is $(6.84 \pm 0.24_{\pm 0.27})\%$. This fraction is 37% larger than the old fraction, and its error is only 27% as large as the old error.

Rather, they have been assigned in accord with expectations of the theory. However, they are all very likely as shown (see below).

SU(4) multiplets—Baryons made from u , d , s , and c quarks belong to SU(4) multiplets. The multiplet numerology, analogous to $3 \times 3 \times 3 = 10 + 8_1 + 8_2 + 1$ for the subset of baryons made from just u , d , and s quarks, is $4 \times 4 \times 4 = 20 + 20'_1 + 20'_2 + \bar{4}$. Figure 2(a) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$.

Figure 2(b) shows the 20'-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon.

Baryon Particle Listings

Charmed Baryons

Figure 2(c) shows the $\bar{4}$ multiplet, an inverted tetrahedron. One level up from the bottom level of each multiplet are the baryons with one c quark. All the baryons in a given multiplet have the same spin and parity. Each N or Δ or $SU(3)$ -singlet- Λ resonance calls for another $20'$ - or 20 - or 4 -plet, respectively.

The flavor symmetries shown in Fig. 2 are of course badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(b), we expect to find, in the same $J^P = 1/2^+$ $20'$ -plet as the nucleon, a Λ_c , a Σ_c , two Ξ_c 's, and an Ω_c . Note that this Ω_c has $J^P = 1/2^+$ and is not in the same $SU(4)$ multiplet as the famous $J^P = 3/2^+$ Ω^- .

Figure 2: $SU(4)$ multiplets of baryons made of u , d , s , and c quarks. (a) The 20 -plet with an $SU(3)$ decuplet on the lowest level. (b) The $20'$ -plet with an $SU(3)$ octet on the lowest level. (c) The 4 -plet. Note that here and in Fig. 3, but not in Fig. 1, each charge state is shown separately.

Figure 3 shows in more detail the middle level of the $20'$ -plet of Fig. 2(b); it splits apart into two $SU(3)$ multiplets, a $\bar{3}$ and a 6 . The states of the $\bar{3}$ are antisymmetric under the interchange of the two light quarks (the u , d , and s quarks), whereas the states of the 6 are symmetric under this interchange. We use a prime to distinguish the Ξ_c in the 6 from the one in the $\bar{3}$.

The observed spectra—(1) The parity of the lightest Λ_c is defined to be positive (as are the parities of the p , n , and Λ); the limited evidence about its spin is consistent with $J = 1/2$. However, few of the J^P quantum numbers given in Fig. 1(a) have been measured. Models using spin-spin and spin-orbit interactions between the quarks, with parameters determined using a few of the masses as input, lead to the J^P assignments shown.[†] There are no surprises: the $J^P = 1/2^+$ states come first, then the $J^P = 3/2^+$ states...

(2) There is, however, evidence that many of the J^P assignments in Fig. 1(a) must be correct. As is well known, the successive mass differences between the $J^P = 3/2^+$ particles, the $\Delta(1232)^-$, $\Sigma(1385)^-$, $\Xi(1535)^-$, and Ω^- , which lie along the lower left edge of the 20 -plet in Fig. 2(a), should according

Figure 3: The $SU(3)$ multiplets on the second level of the $SU(4)$ multiplet of Fig. 2(b). The Λ_c and Ξ_c tabbed with open circles in Fig. 1(a) complete a $J^P = 1/2^+$ $SU(3)$ $\bar{3}$ -plet, as in (a) here. The Σ_c , Ξ_c , and Ω_c tabbed with closed circles in Fig. 1(a) complete a $J^P = 1/2^+$ $SU(3)$ 6 -plet, as in (b) here. Together the nine particles complete the charm = +1 level of a $J^P = 1/2^+$ $SU(4)$ $20'$ -plet, as in Fig. 2(b).

to $SU(3)$ be about equal; and indeed experimentally they nearly are. In the same way, the mass differences between the $J^P = 1/2^+$ $\Sigma_c(2455)^0$, Ξ_c^0 , and Ω_c^0 ,[‡] the particles along the left edge of Fig. 3(b), should be about equal—assuming, of course, that they *do* all have the same J^P . The measured differences are 125.0 ± 2.9 MeV and 117.3 ± 3.4 MeV—not perfect, but close. Similarly, the mass differences between the presumed $J^P = 3/2^+$ $\Sigma_c(2520)^0$, $\Xi_c(2645)^0$, and $\Omega_c(2770)^0$ are 127.1 ± 0.8 MeV and 120.0 ± 2.1 MeV. In Fig. 1(a), these two sets of charm particles are tabbed with solid circles and solid squares.

(3) Other evidence comes from the decay of the $\Lambda_c(2593)$. The only allowed strong decay is $\Lambda_c(2593)^+ \rightarrow \Lambda_c^+ \pi \pi$, and this appears to be dominated by the submode $\Sigma_c(2455)\pi$, despite little available phase space for the latter (the “ Q ” is about 2 MeV, the c.m. decay momentum about 20 MeV/c). Thus the decay is almost certainly s -wave, which, assuming that the $\Sigma_c(2455)$ does indeed have $J^P = 1/2^+$, makes $J^P = 1/2^-$ for the $\Lambda_c(2593)$.

Footnotes:

* The unpromoted states are a $\Lambda_c(2765)^+$, a $\Xi_c(2930)$, and a $\Xi_c(3123)$. There is also very weak evidence for a baryon with *two* c quarks, a Ξ_{cc}^+ at 3519 MeV. See the Particle Listings.

** For example, there are three Ω_c^0 states (properly symmetrized states of ssc , scs , and css) corresponding to each Ω^- (sss) state.

† This is not the place to discuss the details of the models, nor to attempt a guide to the literature. See the discovery papers of the various charmed baryons for references to the models that lead to the quantum-number assignments.

‡ A reminder about the Particle Data Group naming scheme: A particle has its mass as part of its name if and only if it decays strongly. Thus $\Sigma(1385)$ and $\Sigma_c(2455)$ but Ω^- and Ξ_c' .

See key on page 601

Baryon Particle Listings

 Λ_c^+ 

$$I(J^P) = 0(\frac{1}{2}^+) \text{ Status: } ****$$

The parity of the Λ_c^+ is defined to be positive (as are the parities of the proton, neutron, and Λ). The quark content is $u d c$. Results of an analysis of $p K^- \pi^+$ decays (JEZABEK 92) are consistent with $J = 1/2$. Nobody doubts that the spin is indeed $1/2$.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

 Λ_c^+ MASS

Our value in 2004, 2284.9 ± 0.6 MeV, was the average of the measurements now filed below as "not used." The BABAR measurement is so much better that we use it alone. Note that it is about 2.6 (old) standard deviations above the 2004 value.

The fit also includes $\Sigma_c^- \Lambda_c^+$ and $\Lambda_c^{*+} \Lambda_c^+$ mass-difference measurements, but this doesn't affect the Λ_c^+ mass. The new (in 2006) Λ_c^+ mass simply pushes all those other masses higher.

¹ AUBERT,B 05s uses low-Q $\Lambda_c^0 K^+$ and $\Sigma^0 K_S^0 K^+$ decays to minimize systematic errors. The error above includes systematic as well as statistical errors. Many cross checks and adjustments to properties of the BABAR detector, as well as the large number of clean events, make this by far the best measurement of the Λ_c^+ mass.

 Λ_c^+ MEAN LIFE

Measurements with an error $\geq 100 \times 10^{-15}$ s or with fewer than 20 events have been omitted from the Listings.

[a] This branching fraction includes all the decay modes of the final-state resonance.

[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 36 branching ratios uses 57 measurements and one constraint to determine 19 parameters. The overall fit has a $\chi^2 = 39.9$ for 39 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.
